Background and Aims: Adipophilin, a member of PAT family proteins, plays a role in lipid droplet formation in diverse cell types. We previously reported that adipophilin expression was predominant in small lipid droplets and ballooned hepatocytes (BHs) in nonalcoholic steatohepatitis (NASH). Frequent expression of adipophilin in BHs is associated with advanced and/or aggressive diseases (Fujii H, et al., Hepatology 2006;44:199A-200A). In addition, ballooning degeneration in NASH is often accompanied by oxidized phosphatidylcholine (oxPC) localization, which indicates oxidative damage to hepatocytes (Ikura Y, et al., Hepatology 2006;43:506-514). Both adipophilin expression and oxPC localization may participate in pathology of NASH via a common pathway, hepatocyte ballooning. Thus, one can hypothesize that these two phenomena are potentially related. To further address this, we performed the following immunohistochemical analysis. Methods: Liver biopsies from 14 patients with NASH (F/M=10/4; Age, 60±9yr; BMI, 27.6±3.8kg/m2; ALT, 83±39IU) were examined. Disease activity was assessed according to the system of Brunt. Sections were stained with immunoperoxidase using anti-adipophilin (Progen) and anti-oxPC (DLH3), and examined under standard microscopy. Positivity in BHs was semiquantitatively as negative, mild (1-5 positive ballooned cells/10mm2 liver section), or marked (>6 positive cells/10mm2). Double staining was also performed using an immunofluorescent technique. Results: The samples showed diverse grade (2.0±0.9) and stage (2.4±1.0) scores. The presence of adipophilin-positive BHs positively correlated to the grade score (Rs=0.86, p=0.002). OxPC-immunoreactivity was also detected however its presence in BHs was linked with high stage scores (Rs=0.53, p=0.06) rather than grade scores (Rs=0.39, p>0.10). No significant relationship between adipophilin- and oxPC-positivity in BHs was evident as immunofluorescent staining infrequently revealed overlapping expression of adipophilin and oxPC in BHs. Conclusions: Both adipophilin expression and oxPC localization in BHs were definitely associated with the histological severity of NASH. However, these two phenomena seemed to be independent of each other. It is unclear whether this represents different pathophysiological processes in BHs or possibly to antigen modification due to oxidative injury to lipid droplet associated proteins like adipophilin in relation to oxPC.

1126 ASSOCIATION OF AST AND ALT WITH LIVER HISTOLOGY IN ADULTS WITH NAFLD

1Medicine, Johns Hopkins University, Baltimore, MD; 2Epidemiology, Johns Hopkins University, Baltimore, MD; 3NIH/NIDDK, Bethesda, MD; 4Medicine, Indiana University, Indianapolis, IN; 5Gastroenterology/Hepatology, Case Western Reserve, Cleveland, OH; 6St. Louis University, St. Louis, MO; 7Medicine, Duke University, Durham, NC

**Background:** Noninvasively distinguishing nonalcoholic steatohepatitis (NASH) from simple steatosis in people with nonalcoholic fatty liver disease (NAFLD) remains challenging and the role of individual liver enzymes for distinguishing NASH is unclear. **Methods:** We studied 383 adults with biopsy-confirmed NAFLD without other chronic liver diseases who enrolled in the NASH Clinical Research Network and who had liver enzyme levels obtained within 6 months of the biopsy. Liver enzymes were tested on fresh serum locally and biopsies were read centrally by hepatopathologists and classified by consensus using the validated NASH CRN NAFLD Feature Scoring System. We used bivariate and multivariable logistic regression to determine which of AST, ALT or the AST/ALT ratio best discriminates definite NASH from other forms of NAFLD. We also compared areas under receiver operating characteristic curves (AUROC) for NASH in relation to the two enzymes and the ratio adjusting for age, gender, race, BMI, PT, total protein and biopsy length. **Results:** The median age was 48 years; 61% were female, and 83% white. The median AST was 46 U/L, ALT 65 U/L, and AST/ALT ratio 0.70. Overall 62% had definite NASH. In bivariate analyses, the median enzyme levels were all significantly higher in those with NASH compared to those without: AST 54 vs. 38 U/L (p<0.001), ALT 71 vs. 59 U/L (p=0.004), and AST/ALT ratio 0.73 vs. 0.64 (p<0.001). The AUROC was highest for AST [0.69] compared to ALT [0.59] and AST/ALT [0.61]. Subjects with NASH were more likely to be women, and had significantly higher levels of total protein, triglycerides, fasting insulin and HOMA-IR, and longer biopsies (all p<0.01). Surprisingly, age, race/ethnicity and BMI were not significantly associated with NASH. In multivariable analyses, AST remained a better predictor for NASH than either ALT or AST/ALT. The AUROCs for the multivariate models were higher for ALT [0.68, p=0.005] and ALT/AST [0.69, p=0.007], but not significantly so for AST [0.73, p=0.06] than for each enzyme alone. A multivariate model with both AST and ALT did not improve the discrimination for NASH (AUROC 0.74, p=0.20) beyond the multivariate model with AST. **Conclusions:** We found that higher AST, ALT and AST/ALT ratio were all significantly associated with NASH, although AST was more strongly associated and had a higher AUROC for discriminating NASH from other forms of NAFLD. Even in the multivariable model with both AST and ALT, the probability a patient without NASH has a higher discriminating score than a patient with NASH is 26%, indicating that additional non-invasive markers of NASH are needed.

1127 METABOLIC SYNDROME AMONG CHILDREN WITH VARIABLE FEATURES OF NONALCOHOLIC FATTY LIVER DISEASE

Heather M. Patton, Ayunr Unalp, Katherine Yates, Jeffrey B. Schwimmer, Joel E. Lavine; 1UCSD Medical Center, San Diego, CA; 2Johns Hopkins University School of Public Health, Baltimore, MD

**Background:** Nonalcoholic steatohepatitis (NASH) is considered the hepatic manifestation of metabolic syndrome (MetS) in adults. The relation between components of MetS and features of nonalcoholic fatty liver disease (NAFLD) in children has not been characterized. **Aim:** To determine the prevalence and correlates of MetS among children enrolled in a large multicenter NASH trial. **Methods:** Children ages 6-17 years enrolled in the NASH Clinical Research Network (CRN) with laboratory studies and anthropometry within 6 months of liver biopsy were included. The following features of MetS were evaluated: obesity (BMI >97th percentile), hypertriglyceridemia (≥5th percentile), low HDL cholesterol (<5th percentile), hypertension (HTN: systolic and/or diastolic blood pressure ≥95th percentile), and impaired glucose tolerance (IGT; serum glucose 140-199 mg/dL at 2 hours during oral glucose tolerance test). MetS was defined as the presence of ≥3 of these features. Liver biopsies were read by the NASH CRN Pathology Committee and are scored according to criteria by Kleiner et al (Hepatology 2005). **Results:** 131 children, predominantly males (78.6%), median age 12.9 years were studied. 89% were obesity, 30% had hypertriglyceridemia, 21% had low HDL, 53% had HTN, and 17% had IGT. The individual features of MetS were not associated with age, gender, race/ethnicity, or BMI status with the exception of IGT, which was less common among those of Hispanic ethnicity (10% vs. 24%, P=0.03). Overall, 32.8% of children met criteria for MetS: 3.1% had no features of MetS, 29% had 1 feature, 35.1% had 2, 22.1% had 3, and 10.7% had 4 features. Children with MetS did not differ from those without MetS in age, gender, race/ethnicity or Tanner stage but were more likely to be obese (100% vs. 83.9%, P=0.005). The histological features of NAFLD were not associated with MetS (mean ± SD values summarized in table). **Conclusions:** Features of MetS are prevalent among children and adolescents with NAFLD, 10.7% of whom had all 4 evaluated features present. Individual histological features of NAFLD did not vary according to the presence of MetS. The long-term implications of MetS, a cluster of cardiovascular risk factors in adults, needs to be determined in this age group.

Disclosures: The following people have nothing to disclose: Heather M. Patton, Ayunr Unalp, Katherine Yates, Jeffrey B. Schwimmer, Joel E. Lavine
Background: Cigarette smoking, alcohol use, diabetes (DM) and older age have all been linked with histological severity in certain chronic liver conditions. Associations between older age and DM with advanced histological stage in nonalcoholic fatty liver disease (NAFLD) have been suggested however, possible links between cigarette smoking or alcohol history with advanced liver fibrosis have not been studied in NAFLD. Aim: To study the associations between cigarette smoking history, alcohol use, DM and age with advanced fibrosis in patients with NAFLD, controlling for other patient characteristics. Methods: All adult patients enrolled in the NASH Clinical Research Network (NASH CRN) studies between February 2005 and December 2006 who had centrally read liver biopsies were included. Advanced fibrosis was defined as stage 3 or 4 by the validated NASH CRN Histological Scoring System for NAFLD. Significant smoking history was defined as a history of smoking >=10 pack-years. Alcohol consumption (abstinent or not) was derived from the Lifetime Drinking History (LDH) questionnaire based on reported history of lifetime abstinence (referred) or not, without quantification of exposure. Bivariate and multivariate logistic regression analyses were performed. Results: 666 subjects were included; 417 were female. Mean age was 48.5. Advanced fibrosis was present in 29.4%. Smoking history >=10 pack-years was reported 23% subjects. DM was present in 27% of subjects. Lifetime abstinence was reported by 50.2% of subjects. Significant bivariate associations were demonstrated between advanced fibrosis and age, significant smoking history, alcohol usage (versus lifetime abstinence), and DM. Alcohol use, DM, and age were independently associated with advanced fibrosis in the multivariate analysis (see Table); however, the association between >=10 pack-yrs smoking history and advanced fibrosis was not significant. Conclusions: Although a link between smoking and liver fibrosis has been demonstrated in some chronic liver diseases, this link was not found in NAFLD. Advanced fibrosis in NAFLD was linked to alcohol use, DM, and age. The possible association between lifetime abstinence or not and advanced fibrosis in NAFLD is an interesting observation that will be investigated further specifically regarding more detailed lifetime drinking histories.

1130 STUDY OF A POLYMORPHISM IN THE GLUTAMATE-CYSTEINE LIGASE (GCLC) GENE IN NONALCHOLIC FATTY LIVER DISEASE

Claudia P. Oliveira1, Ana Mercedes C. Luna2, Jose T. Stefano1, Telma E. Santos1, Suzana M. Vieira2, Vicenicia M. Rodrigues De Lima1, Maria Angela H Z. Fortes2, Venancio A F. Alves3, Flair J. Carrilho1, Maria Lucia Correa-Giannella2; 1Gastroenterology (LIM-07), School of Medicine of University of São Paulo, São Paulo, Brazil; 2Endocrinology (LIM-25), University of Sao Paulo School of Medicine, Sao Paulo, Brazil; 3Pathology (LIM-14), University of Sao Paulo School of Medicine, Sao Paulo, Brazil

Background & Aims: Recently, considerable attention has been given to the oxidative stress and the defective cellular antioxidant defenses as cause of nonalcoholic fatty liver disease (NAFLD) progression. Glutamate-cysteine ligase is a heterodimer composed of a heavy catalytic subunit (GCLC) which catalyses the first and limiting step in the formation of glutathione, an important endogenous antioxidant. The -129C/T polymorphism of the GCLC gene, in which the T allele is associated with lower promoter activity, was associated with myocardial infarction in the Japanese population. In the Brazilian population, this polymorphism conferred a high risk for nephropathy development (OR=5.95; CI=2.29-15.46; p=0.0002) in patients with type 1 diabetes mellitus, a condition also associated with increased reactive oxygen species production and decreased intracellular antioxidant defenses. The frequency of this polymorphism in the GCLC gene is being preliminary investigated in NAFLD patients. Methods: Genomic DNA was extracted from peripheral blood cells and the promoter region of the GCLC gene was amplified by PCR. The GCLC -129C/T polymorphism was determined by the PCR-based restriction fragment length polymorphism (RFLP). Forty-one patients with NAFLD submitted to hepatic biopsy were divided in two groups: patients with hepatic steatosis (n=9) or steatohepatitis (NASH) (n=32), the latter defined by histologic aspects by NASH Activity Score (NAS) classification devised by the Pathology Committee of the NASH Clinical Research Network. Results: The presence of at least one T allele in the polymorphism -129 of the GCLC gene was higher in patients with NASH (9 out of 32 patients, 28%) than in patients with steatosis (0 out of 9 patients, 0%). Conclusions: Although the small sample size limited our ability to detect any statistically significant difference, further studies in larger populations are guaranteed to evaluate if the polymorphism in the GCLC gene is associated with NAFLD evolution.

1131 INFLUENCE OF IMPAIRED GLUCOSE TOLERANCE, GLUCOSE CONTROL STATUS, LIGHT TO MODERATE ALCOHOL CONSUMPTION, AND REDUCED CARBOHYDRATE DIETS ON SERUM ALT CHANGE DURING RAPID WEIGHT LOSS IN THE RESIDENTIAL WEIGHT LOSS PROGRAM

Ayako Suzuki2, Ronald Sha2, 3, Amy Wachholtz2, 4, Martin Binks2, 4, Anna Mae Diehl1; 1Division of Gastroenterology, Dept. of Medicine, Duke University Medical Center, Durham, NC; 2Duke Diet and Fitness Center, Duke University Health System, Durham, NC; 3Department of Community and Family Medicine, Duke University Medical Center, Durham, NC; 4Division of Medical Psychology, Dept. of Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC

Background: We reported that serum ALT changes following weight loss are influenced by demography, lifestyle, and comorbidities. Rapid weight loss, smoking, sleep apnea, and glucose intolerance were adversely, while hypertriglyceridemia was favorably, associated with serum ALT response following significant weight loss [AASLD 2006]. We hypothesize that extent of fatty acid (FA) delivery to liver FA oxidizing enzymes, activity of FA oxidation, and hepatic redox status influence liver injury during significant weight loss. Aims: To determine how insulin resistance/diabetes (which increase FA delivery to liver), hyperglycemia status (which decreases mitochondrial FA oxidation), reduced carbohydrate (CHO) diets (which decrease de novo hepatic FA synthesis), smoking or alcohol use (which impact hepatic FA oxidizing enzymes and antioxidant defenses) and/or aging (which decreases antioxidant reserves) influence ALT response to rapid weight loss (which increases delivery of exogenous FA to the liver). Methods: Participants in a 4-week residential weight loss program who did not have other liver diseases, or excessive EtOH consumption (<7 women; <14 men, drinks/week) were examined (n=362). The 181 subjects whose rate of weight loss was greater than the median value (1.53 kg/week) were further analyzed. Putative predictor variables and ALT were collected at the baseline. ALT and body weight were re-evaluated at the end of the program. The associations of ALT deterioration (≥10 IU/L increase) with age, BMI, rate of weight loss, baseline ALT, comorbidities including diabetes mellitus/impaired fasting glucose (DM/IFG), serum glucose, high HbA1c (≥7%), current smoking, alcohol use (servings/week), reduced CHO diet during the program (CHO <35% dietary kcal) were assessed by multivariable logistic regression. Results: Total weight loss was 7.7+3.0 kg (2.36±0.67 kg/week). Of this subset, 20% showed ALT deterioration. Faster weight loss (OR=4. for 1 unit increase, p<0.01) and DM/IFG (OR=4.6, p<0.02) were associated with increased odds, while older age (OR=0.8 for 5 units increase, p<0.02), reduced CHO diets (OR=0.1, p<0.04), and possibly up to moderate alcohol consumption (OR=0.8 for 1 unit increase, p=0.08) were associated with decreased odds of ALT deterioration. Conclusions: Findings suggest that among rapid weight losers, ALT deterioration associates with factors that increase hepatic exposure to exogenous FA (faster weight loss, DM/IFG), while factors that reduce hepatic FA synthesis (reduced CHO diets) or induce FA oxidation/antioxidant defenses (light to moderate alcohol consumption) may be protective.

NON-ALCOHOLIC FATTY LIVER DISEASE IS ASSOCIATED WITH TRANSSCRIPTIONAL DYSREGULATION OF THE CORTICOSTEROID METABOLISING ENZYME 11βHSD-1 LEADING TO EXCESS INTRAHEPATIC STEROID EXPOSURE
F. M. Coyle1,3, N. F. Taylor2, J. P. Monson2, W. M. Drake3, G. R. Foster1; 1Gastroenterology, Institute of Cell and Molecular Science, QMUL, London, United Kingdom; 2Clinical Biochemistry, King’s College Hospital, London, United Kingdom; 3Clinical Endocrinology, Barts and the London School of Medicine, London, United Kingdom

Background Glucocorticoids play a key role in determining body fat distribution. Excess circulating glucocorticoids lead to intrahepatic fat accumulation. Obesity is associated with enhanced steroid production but this is offset by enhanced degradation such that circulating steroid concentrations are normal. However, tissue-specific pathways may lead to different degrees of cortisol exposure in different organs. Local steroid exposure in the liver is determined by the activity of the enzyme 11 beta hydroxysteroid dehydrogenase type 1 (11βHSD-1) which converts inactive cortisone to active cortisol. Studies in ‘healthy’ individuals show a reduction in the activity of 11βHSD-1 with increasing BMI thus protecting the liver from the effects of excess cortisol. We tested the hypothesis that in obese people with non-alcoholic fatty liver disease (NAFLD) this adaptive response is impaired leading to enhanced local production of cortisol and steroid-induced steatosis. Methods We measured insulin resistance (HOMA-IR), % body fat (by DXA) and 11βHSD-1 activity/expression in patients with NAFLD/NASH undergoing biopsy and correlated these with the histological features. Global 11βHSD-1 activity was determined by analysis of urinary excretion of cortisol metabolites, with results expressed as a ratio of tetrahydrocortisols (THF, allo THF) over tetrahydrocortisone (THE). Intrahepatic 11βHSD-1 mRNA levels were determined in liver tissue by real-time PCR. Control patients had no-steatotic liver disease (chiefly hepatitis B, HCV patients were excluded). Results 11βHSD-1 activity was significantly higher in the 15 individuals with NAFLD (0.73±0.04) vs controls (0.57±0.03), p<0.02. In the 10 control patients 11βHSD-1 activity decreased with increasing BMI but this was not seen in patients with NAFLD/NASH. These changes in 11βHSD-1 activity were mirrored by changes in mRNA expression of 11βHSD-1 in liver tissue, suggesting that the changes were due to dysregulation of enzyme RNA expression. Thus in obese individuals with fatty liver disease 11βHSD-1 does not down regulate appropriately and this may be due to transcriptional abrogation that may play a role in the development of hepatic steatosis.

NORMAL ALT IN NAFLD SHOULD NOT PRECLUDE LIVER BIOPSY
Anna Ludovica Fracanzani1, Luca Valenti1, Elisabetta Bugianesi2, Giulia Marchesini3, Marco Andreolletti4, Agostino Colli, Cristina Bertelli, Erika Fatta, Silvia Fargion

Patients with NAFLD have an excess mortality for hepatic and extrahaepatic diseases. Some patients with NAFLD have normal ALT levels and it is uncertain whether this reflects a milder disease and whether these patients should undergo liver biopsy. The aim of this study was to compare clinical presentation and histological findings of patients with NAFLD with and without increased ALT. We reviewed a clinical database of Italian patients with NAFLD followed in four liver units (455 cases), who underwent liver biopsy between January 2002-December 2005, referred for abnormalities in liver function tests, dyslipidaemia, hyperferritinemia or for liver steatosis detected by US for non liver related causes. Patients were divided in two groups according to persistently normal ALT values (60 cases) and increased ALT (395 cases). Persistent hyperferritinemia, increased fasting glucose, impaired glucose tolerance or diabetes were the main reasons to biopsy patients with normal ALT. Patients with normal ALT were significantly older (48±10, 43±11 yrs, p=0.001), had significantly lower BMI (23.3±4, 27.4±3.7 Kg/m2, p=0.0001), triglycerides (124±70, 150±87 mg/dl, p=0.02), fasting insulin (13.0±7.3, 19.1±14.8, mIU/l p=0.002), HOMA-IR (3.0±2.0, 4.7±4.7, p=0.006), ALT (29±7, 84±44 IU/l, p=0.0001), and GGT(66±62, 101±14 IU/l, p=0.03), but higher prevalence of impaired glucose tolerance (16%, 8%, p=0.03) and hypertension (33%, 21%, p=0.03). NASH was diagnosed in 62% and 74% (p=0.04) patients with normal or increased ALT. No significant difference in advanced fibrosis (≥2) was observed in patients with (21%) or without (15%) increased ALT. Patients with normal ALT had significantly milder inflammation. At univariate analysis in patients with increased ALT variables significantly associated with fibrosis ≥2 were age (p=0.001), BMI (p=0.01), fasting glucose (0.002), ALT (0.01), ferritin (p=0.001), HOMA-IR (p=0.04) and prevalence of diabetes (p=0.01), while in patients with normal ALT were age (p=0.05), diabetes (p=0.03) and HOMA-IR (p=0.03). At logistic regression analysis, performed only in patients with increased ALT for the small number of patients with normal ALT, serum ferritin (p=0.03), age (p=0.02), ALT (p=0.005), and diabetes (p=0.01) remained independently associated with fibrosis. In the overall series, patients with higher ferritin and ALT level and diabetes were at higher risk to have NASH. In conclusion, our data indicate that also patients with normal ALT should undergo liver biopsy particularly in the presence of diabetes, for an early diagnosis of fibrosis and prevention of progression of hepatic and extrahaepatic diseases.

1134
ULTRASTRUCTURAL EVALUATION OF HEPATOCELLS WITH TYPE 2 MALLORY-DENK BODIES: CLUES TO BALLOONING IN NONALCOHOLIC STEATOHEPATITIS (NASH)
Stephen H. Caldwell1, Jan A. Redick2, Christine A. Davis2, Elizabeth M. Brunt3, Vicencia M. Lima3, Curtis K. Argo1, Abdullah M. Al-Osaimi1, Brent A. Tehrani1, GI/Hepatology, University of Virginia, Charlottesville, VA; 2Advanced Microscopy Facility, University of Virginia, Charlottesville, VA; 3Pathology, Saint Louis University, Saint Louis, MO; 4GI/Hepatology, Saint Louis University, Saint Louis, MO; 5GI/Hepatology, University of Sao Paulo, Sao Paulo, Brazil

Mallory-Denk bodies (MDB), or Mallory’s hyaline, are a common but less frequently encountered form of cell injury in NASH. MDB are often associated with hepatocyte ballooning by light microscopy (Denk et al J Pathol 2006;208:653-661). Although ballooning is one of the most significant light micro-
scopic (LM) findings in NASH, its mechanisms and ultrastructural definition remain controversial (Caldwell et al Am J Gastro 2006;101:1677). We recently completed a prospective, systematic transmission electron microscopic (TEM) survey of 40 liver biopsy specimens from 20 NAFLD patients in which we examined 1,597 grid holes - 40 grid holes per biopsy except one biopsy in which 37 gridholes were examined (Caldwell et al, Hepatology in press). Aim: This systematic study afforded us the opportunity to examine cells containing MDB and consider their possible relationship with other intracellular alterations that may relate to hepatocyte ballooning in NASH. Methods: Grid holes previously identified as containing hepatocytes with well-formed type 2 MDB (irregular intracytoplasmic aggregates of randomly oriented filaments of varying diameter) were identified and reviewed for the following characteristics: hepatocyte diameter >30µ, microsteatosis, dilation of endoplasmic reticulum, and mitochondrial alterations, i.e., crystalline inclusions. Results: MDBs were identified in 6 biopsies. Hepatocytes >30µ were present in 3 of these in association with MDB. The cytoplasm surrounding the MDB contained small droplet fat in 5 of 6 including all of the cells that were also >30µ. Dilated endoplasmic reticulum, often prominent at the border of the MDB, was evident in 5 of 6 samples also including all of those with hepatocytes >30µ. Crystal containing mitochondria were evident in two of six of the samples; neither of which were associated with hepatocytes >30µ. Conclusions: Mallory-Denk bodies occur in both normal sized and enlarged hepatocytes in human NASH. They are often associated with small droplet fat and dilated endoplasmic reticulum, especially in hepatocytes >30µ in diameter. Because MDBs are most easily identified in ballooned cells by LM, and these cells have rarefied cytoplasm, these associations suggest that ballooning in NASH may in part derive from a combination of small droplet fat and dilated ER. We hypothesize that this relationship results from oxidative injury in the rim of the ER-derived small fat droplets (Ikura et al Hepatology 2006;43:506-14) which disrupts trafficking of these droplets and impedes endoplasmic reticulum function.

1135 RELATIONSHIP OF BMI AND THE METABOLIC SYNDROME IN NON-DIABETIC PATIENTS WITH NAFLD

James e. Nelson1, Katherine Yates2, Aynur Unalp2, Kris V. Kowdley1; 1GI, Virginia Mason Medical Center, Benaroya Research Institute, Seattle, WA; 2School of Public Health, Johns Hopkins, Baltimore, MD

Background: The metabolic syndrome (MetS) and nonalcoholic fatty liver disease (NAFLD) are both associated with obesity and increasingly common in the USA. Aim: The aim of this study was to examine the relationship between BMI and MetS in non-diabetic patients enrolled in NASH Clinical Research Network (CRN) studies. Methods: Clinical, demographic, histologic, laboratory and anthropometric data were collected on 356 adult (≥18 yrs) non-diabetic patients with NAFLD. Patients were classified by BMI as follows: ≤24.9-normal weight; 25.0-29.9-overweight; ≥ 30.0-obese. The MetS was determined using the WHO criteria to include three or more of the following features: elevated waist circumference, elevated triglycerides, reduced HDL cholesterol, hypertension and elevated fasting blood glucose. Results: The majority of patients were obese (71%). The prevalence of the MetS was 67%. Obesity was significantly more common among patients with MetS compared to those without MetS (80% vs 52% respectively; p<0.001). The most common feature among MetS patients was elevated waist circumference (93%) followed by hypertension (85%). By contrast, elevated fasting blood glucose was present in only 27% of MetS patients; however, fasting insulin (27.2 vs 21.6 µU/ml, p<0.001), C peptide (4.6 vs 3.3 mg/dl, p<0.001) and HOMA IR (6.5 vs 4.9, p<0.001) were all significantly higher among those with MetS compared to those without MetS. The proportion of MetS patients with mild steatosis (5-33%) was lower compared to those without MetS and greater with severe steatosis (≥66%) suggesting a trend for greater severity (p=0.04). Chronic portal inflammation was more common among those with MetS compared to those without MetS (85% vs 74%; p=0.01). There was no significant difference in the NAFLD activity score or other histologic parameters nor the prevalence of NASH between the two groups (61% MetS vs 53% non-MetS p=0.12). Conclusions: Obesity and MetS are common among non-diabetic patients with NAFLD. These patients have greater insulin resistance compared to non-diabetic NAFLD patients without MetS based on higher fasting blood glucose, HOMA-IR, and fasting insulin and C peptide values. Patients with MetS tended to have more severe hepatic steatosis and chronic portal inflammation compared to those without MetS. However, presence of MetS was not associated with higher NAFLD activity score or fibrosis stage. These data suggest that the clinical and histologic features of non-diabetic NAFLD patients with MetS may be different than in those without MetS. Routine evaluation for MetS should be considered in non-diabetic NAFLD patients and may help guide diagnosis and therapy.

1136 FATIGUE IN NAFLD IS SEVERE AND ASSOCIATES WITH EXCESSIVE DAYTIME SOMNOLENCE BUT NOT WITH LIVER DISEASE SEVERITY OR INSULIN RESISTANCE

Julia L. Newton, David E. Jones, Lara Kane, Elisbeth Henderson, Jessie Pairman, Katharine Wilton, Alastair D. Burt, Christopher P. Day; Institute for Cellular Medicine, Newcastle University, Newcastle, United Kingdom

Anecdotal reports suggest that patients with non-alcoholic fatty liver disease (NAFLD) experience disproportionate levels of fatigue. To date, there has been no attempt to quantify fatigue in NAFLD, to determine the extent to which perceived fatigue reflects true impairment of physical function and to examine the potential causes of this important symptom. We addressed each of these questions in a series of linked studies performed in a fully characterised patient cohort (156 NAFLD patients in total) using optimal methodologies. In phase 1; we explored the degree of fatigue experienced by NAFLD patients (assessed using the fatigue impact scale (FIS) a fully validated fatigue impact assessment tool) in comparison to normal and liver disease controls and its relationship to actual impairment of physical function. Mean FIS was markedly higher in NAFLD patients than in fully age, sex and BMI matched controls (mean FIS 51±38 (possible range 0-160) v 8±12, p<0.0001). NAFLD patients showed significantly lower levels of physical activity than normal controls over 6 days of physical activity monitoring (Actigraphy) (7089±2909 mean steps per day v 8676±2894, p<0.02). Significant inverse correlation was seen between FIS and physical activity (r2=0.1, p=0.02). Fatigue experienced by an appropriately case-matched subgroup of NAFLD patients was similar to that in a group of PBC patients (n=36) [FIS 64±9 v 61±2, p=ns]. Limitation in physical activity was also similar in

Diseases: EXCESSIVE DAYTIME SOMNOLENCE BUT NOT WITH LIVER DISEASE SEVERITY OR INSULIN RESISTANCE

Julia L. Newton, David E. Jones, Lara Kane, Elisabeth Henderson, Jessie Pairman, Katharine Wilton, Alastair D. Burt, Christopher P. Day; Institute for Cellular Medicine, Newcastle University, Newcastle, United Kingdom

Anecdotal reports suggest that patients with non-alcoholic fatty liver disease (NAFLD) experience disproportionate levels of fatigue. To date, there has been no attempt to quantify fatigue in NAFLD, to determine the extent to which perceived fatigue reflects true impairment of physical function and to examine the potential causes of this important symptom. We addressed each of these questions in a series of linked studies performed in a fully characterised patient cohort (156 NAFLD patients in total) using optimal methodologies. In phase 1; we explored the degree of fatigue experienced by NAFLD patients (assessed using the fatigue impact scale (FIS) a fully validated fatigue impact assessment tool) in comparison to normal and liver disease controls and its relationship to actual impairment of physical function. Mean FIS was markedly higher in NAFLD patients than in fully age, sex and BMI matched controls (mean FIS 51±38 (possible range 0-160) v 8±12, p<0.0001). NAFLD patients showed significantly lower levels of physical activity than normal controls over 6 days of physical activity monitoring (Actigraphy) (7089±2909 mean steps per day v 8676±2894, p<0.02). Significant inverse correlation was seen between FIS and physical activity (r2=0.1, p=0.02). Fatigue experienced by an appropriately case-matched subgroup of NAFLD patients was similar to that in a group of PBC patients (n=36) [FIS 64±9 v 61±2, p=ns]. Limitation in physical activity was also similar in
the matched NAFLD patients to that seen in PBC patients (mean steps 7501±1570 vs 7565±2905, p=ns). In phase 2; we examined the biological associations of fatigue in NAFLD. No association was seen between FIS and albumin, bilirubin, alkaline phosphatase, ALT or AST (all r² < 0.005), histological fat score (r² = 0.02), necroinflammatory score (r² = 0.01), fibrosis score (r² = 0.001) or HOMA (r² < 0.005). Significant association was, however, seen between fatigue severity and degree of daytime somnolence assessed using the Epworth Sleepiness Scale (r² = 0.2, p < 0.0001). In conclusion, we have demonstrated that fatigue is a significant problem in NAFLD, is similar in degree to that seen in PBC patients and reflects a true impairment in functional function. Fatigue in NAFLD appears to be unrelated to either severity of underlying liver disease (in terms of either inflammation or fibrosis) or insulin resistance but is associated with significant daytime somnolence. Further study will be required to determine whether the association with sleep disturbance reflects the presence of obstructive apnoea and the degree to which treatments aimed at reducing daytime somnolence are also effective at reducing fatigue in NAFLD.

1137 INFLUENCE OF ADIPONECTIN GENE POLYMORPHISMS IN PATIENTS WITH NONALCOHOLIC FATTY LIVER DISEASE  
Katsutoshi Tokushige, Etsuko Hashimoto, Ayae Kabutake, Mihoko Takakura, Maki Tobari, Storu Yatsuji, Makiko Tanai, Keiko Shiratori; Tokyo Women's Medical University, Tokyo, Japan  
(Aim) Adiponectin is one of the adipo-cytokines associated with insulin resistance, type-2 diabetes, liver fibrosis and the pathogenesis of nonalcoholic fatty liver disease (NAFLD). Single nucleotide polymorphism (SNP) of adiponectin gene has been reported to be associated with insulin resistance and the prevalence of type-2 diabetes. Therefore, we investigated the SNPs of adiponectin, comparing them with the respective clinical and pathological findings. In addition, we also investigated the associations between the SNPs of adiponectin gene and insulin resistance, and plasma adiponectin levels. (Patients and Methods) 106 patients were histologically diagnosed as having NAFLD. The diagnosis of NAFLD was based on three criteria; 1) histologically macrovesicular steatosis affecting at least 10% of hepatocytes, 2) intake of less than 20 g of ethanol per day, 3) appropriate exclusion of other diseases such as alcoholic liver disease, viral hepatitis, autoimmune hepatitis, and metabolic liver diseases. Adiponectin SNP sites were investigated at +45 of Exon 2, +276 of Intron 2, +112 of Exon 3 and +164 of Exon 3, sites indicated as being associated with diabetes or metabolic diseases. Adiponectin SNP sites were investigated at +45 of Exon 2, +276 of Intron 2, +112 of Exon 3 and +164 of Exon 3, sites indicated as being associated with diabetes or metabolic diseases. (Results) 1. Regarding +276 SNP, the frequency of G/G (57.3%) in NAFLD patients tended to be higher than that of control (50.9%), but the difference was not significant. In females only, the G/G frequency (59.6%) was significantly higher than in female control (37%). In addition, the G/G frequency of the severe-fibrosis group was 63.2%, indicating a higher frequency with fibrosis severity. 2. As for +45 SNP, the frequency of T/T (45.6%) in NAFLD patients tended to be lower than that of control, but the difference was not significant. In G/G homozygotes, the frequency of severe fibrosis was significantly higher than that of G/T and T/T genotypes (p=0.003). 3. Regarding +112 of Exon 3 and +164 of Exon 3 SNPs, there were no differences between NAFLD and control. 4. In NAFLD patients with adiponectin +45 G/G, the frequency of HOMA-2 was significantly increased compared with NAFLD patients without adiponectin +45 G/G. 5. In NAFLD patients with adiponectin +276 G/G, plasma adiponectin levels tended to be lower than in those without G/G. In NAFLD patients with adiponectin +45 T/T, plasma adiponectin levels tended to be higher than in those without T/T. (Conclusion) The frequencies of adiponectin SNP sites were significantly different between NAFLD and control in only females. In addition, associations between adiponectin SNP and progression of liver fibrosis and insulin resistance were suggested. In male patients with NAFLD, life style and some other genes might be involved.

1138 HISTOLOGICAL CHARACTERISTICS OF PATIENTS WITH ‘CRYPTOGENIC’ CIRRHOSIS AND PRIOR BIOPSY SHOWING NASH  
Vanessa D. Lee1, David Kleiner2, Abdullah M. Al-Osaimi1, Curtis K. Argo1, Patrick G. Northup1, Carl L. Berg1, Timothy L. Pruet1, Timothy M. Schmitt2, Stephen H. Caldwell1; 1GI/Hepatology, University of Virginia, Charlottesville, VA; 2Clinical Pathology, National Cancer Institute, Bethesda, MD; 3Liver Transplant Surgery, University of Virginia, Charlottesville, VA  
Prior serial biopsy studies have shown that the course of nonalcoholic steatohepatitis (NASH) may include a late stage in which steatosis decreases to the point that NASH is absent or evident only by residual markers of fatty liver disease. However, patients with prior biopsy-proven NASH are seldom re-biopsied if they present with complicated cirrhosis and patients presenting with advanced cirrhosis often lack prior pathological data to prove the existence of antecedent NASH. Aim: To expand the existing data regarding NASH and ‘cryptogenic’ cirrhosis, we sought to further characterize late stage histology in patients with prior biopsies showing unequivocal non-cirrhotic NASH. Methods: Patients were included who had at least two serial biopsies with the initial biopsy demonstrating non-cirrhotic NASH and subsequent biopsies showing cirrhosis without definitive findings of NASH. Controls were chosen from patients with serial biopsies showing NASH without progression to cirrhosis. Biopsy specimens were evaluated in a blinded fashion by a hepatopathologist using the NASCHR-CRN system. Results: 11 biopsy specimens from the 4 patients meeting criteria were included. All patients had a history of ongoing obesity and 3 of 4 were diabetic although only one had a history of thiazolidinedione (TZD) therapy. 3 were female and the age range at the latest biopsy was 41 – 63 yrs. The time between the first and last biopsy was 4 – 14 yrs. Although steatosis declined to trace (<5%) in 3 of 4, residual histological features characteristic of NASH including ballooning (4 of 4), lobular inflammation (4 of 4), Mallory-Denk Bodies (3 of 4) and glycogenated nuclei (2 of 4) were evident in the final specimens. One patient underwent liver transplantation (LT) and we documented progression from ‘NASH with cirrhosis’ on the explant to recurrent NASH with fibrosis 6 years post LT, to incomplete cirrhosis (Ishak stage 5) with only trace steatosis 14 years post transplant. Conclusions: Our results confirm that NASH can progress to a more bland histopathologic entity consistent with prior descriptions of ‘cryptogenic’ cirrhosis. The results also support histological characteristics of late stage NASH that have been used in classification schemes of cryptogenic cirrhosis (Contos, Liver Transpl 2001;7:363 and Ayata, Hum Pathol 2002;33:1098) including minimal steatosis, cellular ballooning, Mallory-Denk bodies, residual lobular inflammation and glycogenated nuclei. We further document post-transplant
recurrence of NASH with progression from histological NASH (year 6 post-LT) to cirrhosis with minimal steatosis (year 14 post-LT).

1139
NAFLD AS A RISK FACTOR FOR THE DEVELOPMENT OF DIABETES AND THE METABOLIC SYNDROME: AN ELEVEN YEAR FOLLOW-UP STUDY
Leon A. Adams1, Oliver R. Waters2, Matthew Knuiman2, Robert Elliott2, John K. Olynky2,3, 1Medicine and Pharmacology, University of Western Australia, Nedlands, WA, Australia; 2Gastroenterology, Fremantle Hospital, Fremantle, WA, Australia; 3Population Health, University of Western Australia, Nedlands, WA, Australia

Objectives: Hepatic steatosis increases hepatic insulin resistance and may therefore predispose to the development of diabetes and the metabolic syndrome. We sought to determine whether nonalcoholic fatty liver disease (NAFLD) with elevated aminotransaminase (ALT) levels was a risk factor for diabetes or the metabolic syndrome (MS) over an eleven year period. Methods: Adult residents of Busselton, Western Australia were assessed in 1994/5 as part of the Busselton Health Survey. NAFLD was diagnosed on the basis of a raised ALT (>40 IU/l) after the exclusion of alcohol, drug toxicity, viral, metabolic and autoimmune liver disease by clinical and serological assessment. Both NAFLD and non-NAFLD subjects were re-visited in 2005 for liver complications, diabetes (fasting glucose >7.0 mmol/l or history) and the metabolic syndrome (MS) as determined by ATPIII criteria. Results: 358 subjects, 68% male, (109 NAFLD, 249 non-NAFLD), mean age (SD) 59.9 (11.6) years, attended follow-up 11.1 years after initial assessment. In 1994/5, those with NAFLD were more likely to have diabetes (fasting glucose >7.0 mmol/l or history) and the metabolic syndrome (MS) (P<0.05 for all comparisons). Non-NAFLD subjects who developed elevated ALT levels on follow-up compared to those whose ALT remained normal, tended to gained more weight (BMI 2.6 (3.0) ± 1.5 (1.9) kg/m2, p=0.059) and had more progressive insulin resistance [HOMA 1.0 (1.4) vs. 0.2 (1.0), p=0.01] between assessments. After excluding subjects with diabetes at baseline, those with NAFLD were more likely to develop diabetes on follow-up (20/106 [18.9%] vs. 15/246 [6.1%], p=0.001). Furthermore, after excluding subjects with MS at baseline, those with NAFLD were more likely to develop MS at follow-up (27/81 [33.3%] vs. 51/226 [22.6%], p=0.056). Using logistic regression analysis, a diagnosis of NAFLD in 1994/5 was also a significant predictor of developing diabetes (r=0.2, p<0.001) and the metabolic syndrome (r=0.58, p=0.058) in 2005. However, a baseline diagnosis of NAFLD became non-significant after adjusting for baseline waist circumference, hypertension and insulin resistance as determined by HOMA. No subjects developed liver complications over the 11 year period. Conclusion: Subjects with NAFLD and elevated ALT levels are at increased risk of developing diabetes and the metabolic syndrome. However this may be due to the presence of associated metabolic risk factors such as central obesity, insulin resistance and hyperglycemia.

ETHNIC AND GENDER DIFFERENCES IN LIVER HISTOLOGY IN OBESITY SURGERY PATIENTS
Eric R. Kallwitz, Grace Guzman, Veronica Tencate, Murdula Kumar, Jamie L. Berkes, Joseph Vitello, Neelima Nadella, Roshan Patel, Thomas J. Layden, Scott Cotler; University of Illinois, Chicago, IL

There are limited data comparing liver histology by ethnicity in patients at risk for NASH, and Hispanics have not been represented in the available series of adult patients. The aim of the current study was to compare liver histology as a function of race and gender in a large, ethnically diverse population of obesity surgery patients. Methods: Case records were reviewed retrospectively from a surgeon who routinely performed liver biopsies during gastric bypass operations over a two year period. All biopsies were scored by a liver pathologist, masked to clinical data, using the NASH Activity Score (Hepatology 2005;41:1313-21). Clinical features were compared by chi square tests for categorical variables and ANOVA or t-tests for continuous variables. Results: 123 of 141 consecutive patients had available clinical data, liver histology, and no evidence of a cause of liver disease other than NAFLD. The ethnic distribution was 46% Non-Hispanic White, 44% African American and 11% Hispanic, by patient self report. There were no significant differences in age, or prevalence of diabetes, hypertension, or hyperlipidemia among the ethnic groups. The mean BMI (kg/m2) was greater in African Americans (55 ± 8), and Non-Hispanic Whites (55 ± 12), than in Hispanics (47 ± 16) [p=0.03]. Overall, 85% of liver biopsies had >5% steatosis and 33% had evidence of NASH (NAS ≥ 5). Steatosis was present in 93% of Non-Hispanic Whites, and 92% of Hispanics, compared to 74% of African American patients (p=0.02). Histologic evidence of NASH was greatest in Hispanics (62%), followed by Non-Hispanic Whites (36%), and African Americans (22%) [p=0.02]. There were no significant differences in lobular inflammation, hepatocellular ballooning, or advanced fibrosis (≥ F2) among ethnic groups, although the number of Hispanic patients was relatively small. Further analysis focused on gender differences. Seventy-six percent of patients were women. The prevalence of steatosis was higher in men (97%) than in women (81%) [p=0.03], although the prevalence of NAS in women was significantly higher in men (34%) and women (32%). Notably, advanced fibrosis (≥ F2) was observed in 48% of men compared to only 22% of women (p=0.007). There were no significant differences in lobular inflammation or hepatocellular ballooning by gender. Conclusions: Examination of liver histology in a large, ethnically diverse group of obesity surgery patients showed that: 1) Hispanics had the highest prevalence of NASH, despite the lowest mean BMI, 2) African Americans had the lowest rates of steatosis and NASH, and 3) men had a higher prevalence of steatosis and advanced fibrosis scores (≥ F2).

INTRODUCTION: Retinol-binding protein 4 (RBP4) has recently been proposed as a new "adipokine" that regulates insulin action in muscles and liver, contributing to insulin resistance. Several studies suggested that RBP4 may play a key role in the pathogenesis of insulin resistance and type 2 diabetes. Non alcoholic fatty liver disease (NAFLD) is related to insulin resistance and obesity. We examined for the first time RBP4 levels in serum and liver in patients with NAFLD.

METHODS: 30 Caucasian patients with biopsy proven NAFLD were included in the study. They had persistently elevated aminotransferases, absence of any other liver disease and alcohol consumption <20gr/d. None had diabetes. 30 healthy controls, matched for age and sex, had been evaluated with a standard oral glucose tolerance test (OGTT). They had normal liver enzymes and abdominal ultrasound and no history of chronic liver disease. None had type 2 diabetes. BMI, ALT, fasting glucose and insulin line, OGTT and homeostasis model assessment of insulin resistance (HOMA-IR) were evaluated. RBP4 was measured by ELISA (AdipoGen). RBP4 expression in liver was examined by immunohistochemistry using a polyclonal antibody to human RBP4 and was semiquantitatively evaluated. Histology specimens were compared with ten normal liver biopsies.

RESULTS: NAFLD patients had significantly higher BMI, HOMA-IR and fasting insulin than controls. Serum RBP4 was significantly lower in NAFLD than in controls (26.14 vs 38.05 µg/mL, p<0.001). There was no significant difference of serum RBP4 between controls with normal and impaired OGTT (36.85 vs 39.25 µg/mL). No difference in serum RBP4 levels was found between patients with simple steatosis and patients with NASH (25.14 vs 25.2 µg/mL). Anti-RBP4 produced granular cytoplasmic hepatocellular immunostaining, which in normal liver was weak and evident in zone 3. In NAFLD cases, RBP4 expression was strongly intense in zone 3 and milder in zones 2 and 1 or perisinusoidal areas. RBP4 score was higher in NAFLD compared to normal liver and was correlated with the grade of steatosis (p<0.01). In NASH, RBP4 score was positively correlated with grade of activity and stage of fibrosis. There was no correlation of RBP4 score with age, serum ALT, BMI or OGTT.

CONCLUSIONS: In patients with NAFLD: a) serum RBP4 levels were significantly lower as compared to controls despite the presence of higher BMI, HOMA-IR and fasting insulin, b) serum RBP4 levels did not correlate with NAFLD disease activity. In contrast patients with NAFLD showed a more intense liver expression of RBP4 compared to controls that was related to grade of steatosis, grade of activity and stage of fibrosis.

NON-ALCOHOLIC FATTY LIVER DISEASE IN CHINESE DOES LEAD TO PROGRESSIVE DISEASE

Chee-Kin Hui1, Nancy Leung2, Sik To Lai3, Jak-Yiu Lai3, Tony Shek4, Hung Yao5, Wai-Ki Li5, George K. Lau1

1Medicine, The University of Hong Kong, Hong Kong, China; 2Medicine, Alice Ho Miu Ling Hospital, Hong Kong, China; 3Medicine, Princess Margaret Hospital, Hong Kong, China; 4Pathology, The University of Hong Kong, Hong Kong, China; 5Pathology, Princess Margaret Hospital, Hong Kong, China

Background: Non-alcoholic fatty liver disease (NAFLD) is an important cause of chronic hepatitis and liver cirrhosis in the West. However, the natural history of NAFLD in Chinese is uncertain. Unlike chronic hepatitis C virus (HCV) infection, the outcome of patients with chronic hepatitis B virus (HBV) infection in the presence of NAFLD is unknown. Aims: To investigate the outcome of Chinese patients with biopsy proven NAFLD compared with chronic HBV infected patients with or without co-existing NAFLD. Methods: Consecutive NAFLD and chronic HBV patients with baseline liver biopsy performed from 1998 to 2002 were included. Patients with liver cirrhosis on liver biopsy or hepatocellular carcinoma on ultrasound at the time of liver biopsy were excluded. Clinical and laboratory parameters related to their liver function and metabolic syndromes were recorded and analyzed. Liver biopsies were scored for degree of steatosis, necroinflammation and fibrosis ( Ishak fibrosis score). Patients were follow-up for a median of 73.1 (range 24.7-109.2) months after liver biopsy. The occurrence of liver complications was recorded. Results: Two-hundred and fifty-eight consecutive patients were studied (92 with chronic HBV, 68 with chronic HBV infection and NAFLD and 98 with NAFLD). Patients with NAFLD had a higher baseline serum bilirubin [median (range) 21 (4-50) vs. 13 (2-56) vs. 11 (4-51) umol/L respectively, p=0.01] and lower baseline platelet level [median (range) 155 (135-364) vs. 185 (139-353) vs. 192 (160-359) k/mm3 respectively, p=0.02] when compared with the chronic HBV and chronic HBV with NAFLD groups. The NAFLD group was also older when compared to the other 2 groups [median (range) 53 (25-86) vs. 38 (17-66) vs. 42 (21-69) years respectively, p=0.02]. There was no significant difference in the baseline liver necroinflammation and fibrosis score among the 3 groups. At the end of follow-up, 20 of the 258 patients (7.8%) had liver complications; 10 patients with uncompensated liver cirrhosis and 10 patients with hepatocellular carcinoma. On Cox proportional hazards analysis, NAFLD group were as likely to develop liver complications as those with chronic HBV infection and chronic HBV infection with NAFLD [8 of the 98 patients (8.2%) vs. 4 of the 92 patients (4.3%) vs. 8 of the 68 patients (11.8%) respectively, p=0.10]. Conclusion: NAFLD is a progressive liver disease in Chinese and more attention should be paid to the diagnosis of NAFLD in Chinese. However, unlike chronic HCV infection the presence of co-existing steatosis does not increase progression of liver disease in chronic HBV patients.

NON-ALCOHOLIC FATTY LIVER DISEASE IN NON-OBESE AMERICAN CHEMICAL WORKERS

Matthew C. Cave1, Arpana Mahalingashetty1, Rehan Khan1, Royce Groce1, Lark Reynolds2, Makunda Ray2, Craig J. McClain1,2, 1Medicine/Gastroenterology, University of Louisville, Louisville, KY, 2Louisville VAMC, Louisville, KY

Background: Occupational exposure to monomeric vinyl chloride (VC) is a well documented risk factor for the development of the rare liver tumor, angiosarcoma, but it has not been associated with NAFLD. Here, we document a high prevalence of advanced NAFLD in non-obese American VC workers. Following the identification of a cluster of hepatic angiosarcoma in VC workers at a single plant in Kentucky in 1974, a liver cancer screening program was begun. Between 1974 and 1976, baseline liver biopsies were obtained from 82 workers with exceptionally high VC exposures. Although NAFLD was not recognized until 1980, the original pathologist documented the presence of “fatty metamorphosis” and “lipoid granulomas”. We reviewed the original pathology reports and clinical data to calculate the prevalence of NAFLD in this group. The original slides from 26 of the 82 workers were available to be over-read by a single expert liver pathologist who, when relevant, graded and staged them by the Brunt criteria. Fatty liver disease was present in 46 workers (56%). They were all white males with an extremely high mean cumulative vinyl chloride exposure of 13,000 PPM-Yr (+5950, s.d.). Their mean age was 45 (+8) and mean body mass index was 26.6 kg/m2 (+4.05). While 10 of these employees reported at least some alcohol intake, only 3 consumed 3 or more drinks daily. Liver chemistries including mean AST (30.6±25.9 IU/L) and ALT (30.9±45.6 U/L) were usually normal. Although the mean serum hyaluronic acid (34±44 µg/L) was normal in most workers with fatty liver, it was elevated in 4 workers who either had or went on to develop angiosarcoma (269±333 µg/L). In the 26 over-read biopsies, the prevalence of hepatic steatosis was 81% and the prevalence of steatohepatitis (NASH) was 77%. While all biopsies originally read as “fatty metamorphosis” had NASH, others without this finding actually had mild NASH. The liver biopsies demonstrated typical morphologic features of NASH including macrovesicular steatosis, Mallory’s hyaline, ballooning degeneration, lipogranulomas, and inflammatory infiltrate. Sinusoidal dilation, an atypical finding for NAFLD, was noted in 80% of cases. 55% of NASH biopsies demonstrated fibrosis and 1 employee had cirrhosis. Three employees with NASH had repeat liver biopsies in 1-6 years. Two of the 3 showed worsening inflammation and fibrosis despite removal from the workplace. This group of American VC workers had a high prevalence of advanced NAFLD unexplained by obesity. This study highlights a potential role for industrial toxins in the development of NAFLD.

A NEW APPROACH IN THE TREATMENT OF PATIENTS WITH NASH—RESULTS OF A PILOT STUDY

Adriana Popescu; Internal medicine, Fundeni Clinical Institute Bucharest, Bucharest, Romania

BACKGROUND: Trimetazidine (Tmz) is a metabolic anti ischemic drug largely used in cardiology to treat angina. Ear-
lier studies using animal models have shown that Tmz produces a shift from mitochondrial fatty acid beta-oxidation to glucose oxidation, associated with down regulation of PPARalpha. NASH, usually associated with obesity, diabetes, hyperlipidemia, hyperinsulinemia and insulin resistance could benefit from the improvement in oxidative stress and ischemic conditions by Tmz. AIM: Trial of Tmz in the treatment of patients with NASH, on the hypothesis of improving liver histology and insulin resistance. METHODS: 24 histologically confirmed cases of NASH received Tmz 70 mg/day (gr.1), for 6 months, compared to 20 patients with NASH (gr.2) receiving placebo (vitamin E) in a randomised fashion. Liver morphometry, oral glucose tolerance test, plasma insulin, insulin sensitivity, aminotransferases, glucose, triglyceride, cholesterol, were followed up before and after 6 months. RESULTS: Elevated fasting serum glucose found in 10/24 patients from gr.1 and 8/20 from gr.2 and impaired glucose tolerance in 12/24 patients from gr.1 and 10/20 from gr.2, normalized in 83% of Tmz treated patients compared to none in placebo. Aminotransferases diminished by 75% in Tmz group vs. 22%. Hyperinsulinemia recovered in all patients from gr.1 vs.10% in gr.2, also insulin /glucose ratio (0.5 vs. 0.92) and hypertriglyceridemia (in 50% patients from gr.1). Liver morphometry index [grading and staging by rebiopsy after 6 months] improved in 75% of patients receiving Tmz vs. .10% in placebo, with no side effects. CONCLUSION: Trimetazidine seems to be a promising agent to ameliorate ischemic conditions in NASH, improving ATP level and oxidative stress. The treatment provided substantial metabolic and clinical benefits in patients with NASH, with respect to liver inflammation and fibrosis, diabetes, insulin resistance and hypertriglyceridemia.

1146 A NASH PREDICTIVE INDEX (NPI) FOR USE IN PATIENTS WITH NONALCOHOLIC FATTY LIVER DISEASE
Claudia O. Zein1, John M. Edmison2, Mark Schluchter3, Ariel E. Feldstein2, Nizar N. Zein2, Arthur J. McCullough2
1Gastroenterology and Hepatology, Case Western Reserve University, Cleveland, OH; 2Division of Gastroenterology and Hepatology, Cleveland Clinic, Cleveland, OH; 3Biostatistics and Epidemiology, Case Western Reserve University, Cleveland, OH

Background: A third of the U.S. population may have nonalcoholic fatty liver disease (NAFLD). Nonalcoholic steatohepatitis (NASH) is associated with progression. Identification of patients with NASH before the onset of advanced fibrosis would help recognize patients who would benefit most from aggressive interventions. Liver biopsy, the only accepted method for NASH identification, is invasive, costly, risky, and limited by sampling variability. Aim: To build a predictive model that would allow identification of NASH among patients with suspected NAFLD. Methods: Data were prospectively collected on consecutive patients with suspected NAFLD seen at an academic medical center in Cleveland between 2004-2006. An independent validation cohort seen at a separate institution between 2005-2006 was identified. Demographic, clinical, metabolic, and laboratory parameters were recorded. The homeostatic model assessment 2 (HOMA-2) was used to calculate HOMA-IR. Those on insulin therapy were excluded. Log transforms of variables with skewed distributions were used. Statistical analyses were done. A scoring system was created. Results: 177 patients were included. In the original cohort (n=122), mean age was 49; 80/122 (66%) were female; 34/122 (28%) were diabetic; and 84/122 (69%) had NASH. Subjects with NASH were older, had higher BMI, HOMA-IR, AST and ALT. By multivariate analysis, age, BMI, HOMA-IR, female sex, and log (ASTxALT) were independent predictors of NASH. A NASH Predictive Index (NPI) was created based on the model (Table). The area under the ROC curve for the NPI was 0.87 (95% CI, 0.81, 0.93). In the validation set (n=55), the AUC was 0.85 (95% CI, 0.75, 0.95). The ROC curves were not statistically different (p=0.68). A NPI value >=6 identified 56% of NASH cases in the original cohort with 100% positive predictive value (PPV), and 65.7% of NASH cases in the validation cohort with 95% PPV. Conclusions: 1. The NPI allowed identification of a significant proportion of patients with NASH, non-invasively and with a high positive predictive value; 2. The NPI, after further validation, may aid in the identification of a significant proportion of NASH cases, patients that will benefit most from aggressive interventions and future therapies, while avoiding liver biopsy.

Logistic regression model for prediction of NASH*

1147 PHOSPHOPROTEOMIC BIOMARKERS PREDICTING WEIGHT LOSS AFTER BARIATRIC SURGERY IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE (NAFLD)
Valerie S. Calvert1,2, Clare Nugent1, Rochelle Collantes1,3, Hazem Elariny1, Arian Afendy1, Ancha Baranova1, Yun Fang1, Jiang-hong Deng1,2, Zachary Goodman4, Lance A. Liatta1,2, Emanuel F. Petricoin1,2, Zobair M. Younossi1,3,4
1Translational Research Institute, Inova Health System, Annandale, VA; 2Center for Applied Proteomics and Molecular Medicine / Department of Molecular and Microbiology, George Mason University, Manassas, VA; 3Center for Liver Diseases, Inova Health System - Inova Fairfax Hospital, Annandale, VA; 4Armed Forces Institute of Pathology, Washington, DC

Central adiposity and metabolic syndrome are associated with NAFLD. Weight loss through bariatric surgery has been associated with resolution of obesity-related complications, including insulin resistance and NAFLD. AIM: To develop a prognostic biomarker to predict successful weight loss after bariatric surgery. METHODS: 111 patients undergoing bariatric surgery were included [age 44+/=11 yrs, 29% male, 99% NAFLD, ALT 33+/=23 IU/L and AST 26+/=19 IU/L]. Clinical and demographic data was obtained at the time of surgery. A liver biopsy was performed and interpreted by a single hepatopathologist. A biopsy of omental fat/white adipose tissue (WAT) was obtained as well as serum which were both snap-frozen. Follow up data was also collected 10.25 +/-9.79 months after surgery. Successful weight loss was defined as losing >50% excess body weight (EBW) or achieving a normal waist circumference (=40 inches in men and <35 inches in women). From WAT, protein lysate was extracted and then used for Reverse Phase Protein Microarray analysis, which quantitatively measured the relative phosphorylation of 80 specific signaling molecules. Parametric and non-parametric analyses...
were performed to compare the cell signaling networks of those patients achieving successful weight loss to those without successful weight loss post-bariatric surgery. RESULTS: Comparing patients who achieved successful weight loss by normalizing their waist circumference to those who did not, the phosphorylation of 17 proteins [pAKT(S473), pERK (T202/Y204), pMEK1/2 (S217/221), pp38 (T180/Y182), pmTOR [S2448], pBAD [S155], penoS (1177), pFAF [S194], pPyk2 (Y402), pFHKR/FKHRL1 (T24/32), pGSK3α/β (S21/9), pp90RSK (S380), pSTAT3 (S277), pCREB (S133), pBAD (S112), pERα (S118) and pAMPKα1 (S485)] were significantly different (P<0.05). If successful weight loss was defined as achieving >50% EBW loss, the phosphorylation levels of 14 proteins [pAKT (S308), pmTOR (S2448), pRasGRF (916), pp70S6 (T389), ClCasase3 (D175), pBAD (S155), pc-Abl (T735), pPyk2 (Y402), pp90RSK (S380), pPKCa/BII (T638/641), pSMAD (S645/647), pSrc (Y527), pBAD (S112) and Cox2] were significantly (>0.05) different in those who achieved success. Nearly all of these proteins are within apoptosis control pathway or insulin/AKT/growth factor signaling pathways.

CONCLUSIONS: Signal pathway profiling using Reverse Phase Protein Microarrays of WAT appears to predict successful weight loss in obese patients with NAFLD after bariatric surgery.

1149 DIRECT COMPARISON OF TWO NON INVASIVE BIO-MARKERS FOR THE DIAGNOSIS OF ADVANCED FIBROSIS IN PATIENTS WITH NON ALCOHOLIC FATTY LIVER DISEASE (NAFLD) : NAFLD SCORE AND FIBROTEST
Monna Munteanu2, Frederic Charlotte1, Vlad Ratziu1, Sophie Jacqueminet1, Djamila Messous1, Philippe Podevin2, Laurence Serfaty3, Eric Bruckert1, Andre Grimald1, Thierry Paynard1,1; APHP GHPS, Paris, France; 2Biopredictive, Paris, France; 3APHP Cochin, Paris, France; 4APHP StAntoine, Paris, France

Background and aims: Patients with NAFLD and advanced liver fibrosis are at the highest risk for progressing to end stage liver disease. The aim was to directly compare two biomarkers that have been separately validated for the noninvasive diagnosis of advanced fibrosis in NALFD, the FibroTest (FT) and the NAFLD score (NS). Methods: Two populations of two prospective studies, initially, were included in the present study when FT and FN were available at the time of liver biopsies. One “diagnostic” cohort initially included 267 patients with baseline biopsy and one randomized trial with rosiglitazone or placebo with baseline and end of 1yr treatment paired biopsies included 63 patients (total biopsies n=126). The primary end point was a difference in area under the ROC curves (AUROC) for the diagnosis of advanced fibrosis defined as septal or bridging fibrosis or cirrhosis (Kleiner et al scoring system).

Results: A total of 246 cases with biopsy, FT and NS were included; these were not significantly different than the nonincluded cases for the main characteristics. The trial patients had more severe liver injury than the cohort patients: the prevalence of advanced fibrosis was 31% and NASH 100% versus 12% and 32% in the cohort. FT and NS both had very significant diagnostic value (P<0.001 versus 0.50 AUROC) for the diagnosis of advanced fibrosis (figure), but the FT AUROC was significantly higher than the NS AUROC both in the diagnostic cohort 0.89 (95%CI 0.81-0.94) vs 0.76 (95%CI 0.59-0.86 ;P=0.035. n=120) and in the therapeutic trial: 0.80 ;95%CI 0.71-0.88 vs 0.70 ;95%CI 0.60-0.78 ;P=0.04 n=126). There was no significant heterogeneity for the FT and NS AUROCs between the two studies results. Conclusion: FibroTest had better diagnostic value than the NAFLD score for the diagnosis of advanced fibrosis among patients with NAFLD in two retrospective analyses; however these differences must be confirmed prospectively.
Background and aims: Physical activity (PA) is commonly recommended for patients with NAFLD. However, evidence that PA is effective in NAFLD prevention and treatment is scarce. Aims: To examine the association between self-reported PA and NAFLD. Methods: A cross-sectional study of a sub-sample (n=375) of the Israeli National Health and Nutrition Survey. Exclusion criteria were any known etiology for secondary NAFLD. Participants underwent an abdominal ultrasound, biochemical tests and anthropometric evaluations (abdominal obesity defined as waist circumference >88 cm in women and >102 cm in men). During a face-to-face interview a detailed PA (leisure and occupational) questionnaire was administered including the name of the PA, its frequency and duration and how long did the subject engaged in the PA [multiplication of all categories was defined as “score”]. Results: After exclusion 349 subjects (52.7% male, mean age 50.7±10.4, 30.9% primary NAFLD) were included in the analysis. No association was found with occupational PA. The NAFLD group as compared to subjects with normal liver performed less than the half of the amount of all kind of sports (32.1 minutes/week vs. 67.3, P=0.001), almost half the amount of aerobic exercise (23.2 minutes/week vs. 42.3, P= 0.03) and only one third the amount of anaerobic exercise (8.9 minutes/week vs. 25.0, P=0.001). Adjusting for age and gender, performance of all kind of sports [OR=0.66, 0.44-0.96 95% CI per 413.2 increment in score units [1 SD]] and anaerobic exercise [OR=0.61, 0.38-0.85 95% CI per 162.5 increment in score units [1 SD]] were inversely associated with NAFLD. The association with anaerobic exercise remained significant with further adjustment for BMI [OR=0.61, 0.44-0.85 95% CI]. Only anaerobic exercise was associated with a lower rate of abdominal obesity irrespective of BMI, gender and age (P=0.03). Among NAFLD patients, performance of PA was associated with lower fasting serum insulin levels (25.7 vs. 32.0, P=0.03) and waist circumference (99.8 vs. 104.7, P=0.04) though BMI was similar. Moreover, performance of PA was associated with a lower rate of abdominal obesity irrespective of BMI, gender and age (OR=0.25, 0.07-0.93 95% CI). Conclusions: Higher leisure-time PA may protect against NAFLD. The protective role of anaerobic exercise can stem from its independent association with a lower rate of abdominal obesity. NAFLD patients that perform PA benefit lower insulin levels irrespective of BMI, probably mediated by a lower rate of abdominal obesity.

SEVERITY OF NON-ALCOHOLIC FATTY LIVER DISEASE IS RELATED TO MTHFR 677C>T HOMOZYGOITY, LOWER GLUTATHIONE AND INSULIN RESISTANCE
John M. Edmison, Srinivasan Dasarathy, Satish C. Kalhan, Arthur J. McCullough; Department of Gastroenterology and Hepatology, Cleveland Clinic, Cleveland, OH

Background & Aims: Non-alcoholic fatty liver disease (NAFLD) is a spectrum of disease ranging from simple steatosis to non-alcoholic steatohepatitis (NASH) and is the most common chronic liver disease in the United States. Hepatic lipid accumulation and peroxidation with generation of reactive oxygen species and unopposed oxidative stress have been implicated in the pathogenesis of NASH. We hypothesized that insulin resistance (IR) and altered hepatic lipid metabolism cause perturbations in methionine-homocysteine metabolism, which are related to severity of liver injury and is compounded by methylenetetrahydrofolate reductase (MTHFR) 677C>T homozygosity. MTHFR is involved in the formation of N5-MTHF, the source of methyl groups for the conversion of homocysteine to methionine. The relation between magnitude of IR, MTHFR 677C>T homozygosity and alterations in the methionine-homocysteine transsulfuration pathway were examined in subjects with biopsy-proven NAFLD. Methods: 48 subjects with histologically diagnosed NAFLD (15 steatosis, 33 NASH) and 25 controls were studied after a 12 hour fast. IR was determined by HOMA; plasma glutathione, methionine, homocysteine and cysteine levels were measured with high-performance liquid chromatography; and MTHFR 677C>T polymorphism was determined by polymerase chain reaction. Results: Plasma glutathione levels were lower (P<0.017) and homocysteine and cysteine levels higher (P<0.017) in subjects with NASH. IR (HOMA) was higher (P<0.0001) in subjects with steatosis and NASH compared with controls. Severity of IR (HOMA > 2.5) was associated with a higher degree of steatosis, hepatocellular ballooning, hepatic fibrosis, and NASI activity score. The frequency of TT homozygosity for the MTHFR polymorphism was higher in subjects with steatosis (13.3 %) and NASI (18.2 %) compared with controls (4 %). Conclusions: Our data show that NASH is associated with perturbations in glutathione and methionine metabolism. Reduced levels of glutathione (the major antioxidant in the liver) may result from the effect of IR on γ-glutamyl-cysteine synthetase, the enzyme utilized in the conversion of cysteine to glutathione. The higher clustering of MTHFR 677C>T homozygosity in NAFLD may have compounded the hepatic injury by impairing the methylation of homocysteine to methionine. The present study provides a metabolic rationale for the progression of NAFLD. Additionally, severe IR (HOMA > 2.5), low plasma glutathione and presence of MTHFR 677C>T homozygosity are associated with NASH. These markers, in combination, may help in the non-invasive diagnosis of NASH as well as provide a rationale for potential new therapies.

Disclosures:
Background: Current upper limit of normal (ULN) for alanine aminotransferase (ALT) level was set at 40 IU/L regardless of age, sex or risk factors for fatty liver diseases (FLD). A recent Italian study suggested that the ULN for ALT should be adjusted to 30 IU/L for men and 19 IU/L for women by eliminating the influences of risk factors for FLD. However, there has been no data on Asian population, especially subjects with normal liver histology. We, therefore, investigated the normal range of ALT level for healthy Korean subjects. Method: We reviewed the medical records of 23,233 subjects who were examined at Health Promotion Center, Asan Medical Center, from January 2005 to April 2006. Questionnaires about past medical illness, medication, alcohol, and smoking were taken from all the study subjects. Subjects were excluded from the analysis if they had any of the followings: current medication, alcohol consumption>40 g/week), DM, hyperlipidemia or positive results on HBsAg or anti-HCV. Subjects were further stratified according to USG findings for FLD, sex, and body mass index (BMI). The UL was defined as 95th percentile. To validate the UL obtained from 'presumed' healthy subjects, we compared with that of 538 living liver donors. They were negative for, HBsAg and anti-HCV, and showed normal histology on liver biopsy.

Results: 1) The ULs for ALT in subjects with normal USG finding and BMI were 36 IU/L in men and 26 IU/L in women 2) Among those with normal USG finding and high BMI (>25), the ULs were 42 IU/L in men and 31 IU/L in women. 3) Presence of fatty change on USG significantly increased the ULs for ALT even in subjects with normal BMI (56 and 43 IU/L). 4) The ULs of ALT were highest in subjects with high BMI and fatty change on USG. They were 88 IU/L in men and 56 IU/L in women. 5) BMI and Triglyceride significantly affected the ULs of ALT, even in subjects with normal USG finding and BMI. 6) The ULs for ALT in normal living liver donors were 35 IU/L for men and 25 IU/L for women, which were comparable to those of the group with normal USG finding and BMI. Conclusion: Overweight and fatty change on USG significantly increased ALT levels, suggesting that subjects at high risk for FLD cannot represent normal population. However, ALT levels increased with BMI and TG, even in subjects at low risk for FLD. The ULN for ALT in Asian subjects are 35 IU/L for men and 25 IU/L for women, which were higher than those in Italian study. This discrepancy was probably due to the fact that our participants had higher BMI than those in Italian study. Therefore, the ULN for ALT obtained from young Western population cannot be used as a reference for Asian subjects.

Disclosures: The following people have nothing to disclose: Jae Keun Lee, Han Chu Lee, Kyoung Hoon Lee, Kang Mo Kim, Young Suk Lim, Young-Hwa Chung, Yung Sang Lee, Dong Jin Suh.
Background: Nonalcoholic fatty liver disease (NAFLD) includes a spectrum of hepatic steatosis, steatohepatitis, fibrosis, and cirrhosis. NAFLD is considered the hepatic representation of the metabolic syndrome and, to date, no effective drug therapy exists. Thus there is a need to expand our current understanding of its pathophysiology and explore novel therapeutic pathways. The renin-angiotensin system (RAS) is crucial in blood pressure regulation and plays a vital role in the pathogenesis of hypertension. Accumulating evidence suggests that RAS exerts deleterious effects through the production of reactive oxygen species (ROS). We hypothesized that increased RAS activity causes NAFLD due to increased hepatic oxidative stress. Methods: We employed a transgenic TG(mRen2)27(Ren2) hypertensive rat model, harboring the mouse Ren2 gene with elevated local RAS activities and Ang II levels. Hepatic indices for steatosis, inflammation, fibrosis, and oxidative stress were assessed and compared with normotensive Sprague-Dawley (SD) controls at ages of 8 and 12 weeks. The causative relationship between Angiotensin II, oxidative stress, and NAFLD were further evaluated by treating groups of 5 week old Ren2 rats (n=6-7 per group) with the angiotensin receptor blocker valsartan (30 mg/kg/day) or the superoxide dismutase/catalase mimetic tempol (1 mM) followed by sacrifice at 12 weeks of age. Hepatic indices for steatosis, inflammation, fibrosis and oxidative stress were assessed and compared with normotensive SD controls. Results: 8-week Ren2 rats developed significant hepatic steatosis, oxidative stress, and NAFLD were further evaluated by treating groups of 5 week old Ren2 rats (n=6-7 per group) with the angiotensin receptor blocker valsartan (30 mg/kg/day) or the superoxide dismutase/catalase mimetic tempol (1 mM) followed by sacrifice at 12 weeks of age. Hepatic indices for steatosis, inflammation, fibrosis and oxidative stress were assessed and compared with normotensive SD controls. Results: 8-week Ren2 rats developed significant hepatic steatosis, oxidative stress, and NAFLD were further evaluated by treating groups of 5 week old Ren2 rats (n=6-7 per group) with the angiotensin receptor blocker valsartan (30 mg/kg/day) or the superoxide dismutase/catalase mimetic tempol (1 mM) followed by sacrifice at 12 weeks of age. Hepatic indices for steatosis, inflammation, fibrosis and oxidative stress were assessed and compared with normotensive SD controls. THE ZEBRAFISH FOIE GRAS MUTANT IS A MODEL OF FATTY LIVER DISEASE WITH ACTIVATED UNFOLDED PROTEIN RESPONSE
Ayca Cinaroglu, Smita Gopinath, Katherine Krahn, Kirsten C.Sadler; Division of Liver Disease/Dept. of Medicine and Dept. of Molecular Cell and Developmental Biology, Mt. Sinai School of Medicine, New York, NY

Hepatic fat accumulation (steatosis) is a frequent consequence of obesity and insulin resistance, and is considered the hepatic manifestation of metabolic syndrome. Steatosis predisposes hepatocytes to further damage, apoptosis and inflammation, which may progress to steatohepatitis and end stage liver disease. Recent studies indicate that activation of the unfolded protein response (UPR) and endoplasmic reticulum (ER) stress as important cellular processes leading to steatosis and hepatic insulin resistance. However, the interplay between hepatic damage, lipid accumulation and UPR activation is not understood. This study describes the zebrafish foie gras mutant embryos as a system for delineating the mechanism linking UPR activation and steatosis. The foie gras gene is highly conserved in animals, has only been studied in zebrafish and its function is uncharacterized. Mutation in foie gras results in hepatomegaly, steatosis, decreased hepatic function and hepatic apoptosis by day 5 of development, with 100% penetrance. Marked increase in the expression in a panel of genes, including bip (22-fold), chop (53-fold) and spliced xbp1 is found in the liver of MT embryos, signifying the specificity of this process. Importantly, gene expression analysis shows that activation of UPR occurs prior to the development of steatosis and hepatic damage, suggesting this to be a cause of steatosis. Moreover, Wild type embryos treated with tunicamycin to induce UPR activation phenotypically the morphological and molecular features of foie gras mutants. This indicates that activation of the UPR is sufficient for steatosis. We hypothesize that mutation in the foie gras gene leads to the activation of UPR and consequently results in steatosis and propose the foie gras mutant as a model to study the relationship between UPR and fatty liver disease.

C-REACTIVE PROTEIN INDUCES INSULIN RESISTANCE IN BOTH HUMAN HEPATOCYTES AND ADIPOCYTES
Adeline Bertola1, Rodolphe Anty1,2, Stephanie Bonnafous2, Yannick Le Marchand-Brustel2, Albert Tran1,2, Philippe Gual2; 1Pôle digestif, Centre Hospitalier universitaire, Nice, France; 2INSERM U568, Nice, France

Introduction: C Reactive Protein (CRP) is a nonspecific marker of inflammation which is elevated in obesity (~ 10 mg/l). We and others have shown that the liver but also the adipose tissue can produce CRP which might contribute to the elevated plasma CRP levels found in obesity. Since CRP could promote specific biological responses, we evaluated the role of local CRP production in human hepatocytes and adipocytes in the insulin signaling and its potential contribution in liver complications. Patients and Methods: This study was done in HepG2 cells and human adipocytes. After isolation of the pre-adipocyte cells in subcutaneous adipose tissue from abdominalplasty, the cells were differentiated into adipocytes. Insulin-stimulated glucose uptake, and CRP-induced lipolysis were evaluated in vitro. IRS1, IRS2 and SOCS3 gene expression was determined by Real-Time PCR. The expression levels of IRS1 were also evaluated by western blot analysis. Results: The long-lasting treatment of HepG2 with a high CRP concentration (10 mg/l for 24h) enhanced the gene expression of SOCS3, protein known to alter insulin signaling by binding with the IRS proteins and Insulin Receptor. Furthermore, the gene expression of both IRS1 and IRS2 was strongly decreased in response to CRP. In human adipocytes, a long-lasting treatment with a high CRP concentration (10 mg/l for 48h) strongly decreased insulin-stimulated PKB activation and glucose uptake, while a low concentration of CRP was without effect (1 mg/l). Moreover, the treatment of adipocytes with a high CRP concentration strongly decreases the expression of Insulin Receptor Substrat-1 at the protein level. The decrease in the amount of the major substrate of Insulin Receptor strongly reduced its action. Finally, the lipolysis was also stimulated by CRP stimulation leading to a strong increase in free fatty acids release from the adipocytes. Conclusion: These data provide the first evidence that in vitro CRP promotes insulin resistance in human hepatocytes and adipocytes. Since insulin-resistance is responsible for the development of steatosis and steatohepatitis, the enhancement of insulin resistance by CRP could contribute to the development of liver complications. CRP acts directly in the liver by inhibiting insulin signaling in hepatocytes and indirectly via the adipose tissue. In adipocytes, CRP stimulates the lipolysis and consequently provides fatty acids for the liver which could lead to the accumulation of triglycerides and hepatic steatosis.

MB07811, A HEPDIRECT PRODRUG OF A LIVER-TARGETED THYROID HORMONE RECEPTOR (TR) AGONIST, AND OTHER SYNTHETIC NON-LIVER-TARGETED TR AGONISTS, BUT NOT T3, REDUCE HEPATIC STEATOSIS
Edward E. Cable, Xiaohong Yang, Patricia D. Finn, Jian Li, Jeffery W. Stiebins, Michael P. Haughey, Jinzhao Hou, Bruce R. Ito, Paul D. van Poelje, David L Linemeyer, Mark D. Erion; Metabasis Therapeutics, La Jolla, CA

MB07811, an orally active HepDirect prodrug of MB07344 (a livers-targeted TR-β agonist), is currently undergoing clinical trials for the treatment of hyperlipidemia. Thyroid hormones (T3, and T4), known to reduce plasma cholesterol levels, also mobilize fatty acids (FA) from the periphery and induce hepatic lipogenic gene expression potentially causing hepatic steatosis. Therefore, the purpose of these studies was to assess the effects of MB07811 on whole body and liver lipid metabolism compared to those elicited by T3, and other TR agonists. Methods: Isolated primary rat adipocytes were used to test for lipolytic effects of TR agonists. Sprague Dawley (SD) rats, Zucker-diabetic fatty rats, ob/ob mice and diet-induced obese (DIO) mice were treated with test agents for up to 11 weeks. Endpoints measured were epididymal fat pad (EFP) weights; liver lipids, histology, mRNA levels; and plasma acyl-carnitine levels. Results: Initial characterization of TR agonists in SD rats demonstrated that T3 decreased EFP weights but not liver triacylglycerol (TG) levels. In contrast, the four synthetic TR agonists tested decreased liver TG levels but did not change EFP weights. Further characterization of MB07811 in animal models of hepatic steatosis indicated that the decrease in liver TG levels occurred across all the animal models tested. T3 consistently decreased peripheral fat with little or no effect on liver TG levels, whereas in the ob/ob mouse, a model with elevated transaminases, clearance of hepatic TG levels correlated with decreases in plasma AST and ALT levels. In DIO mice, hepatic levels of both TGs and diacylglycerols, a key mediator of hepatic insulin resistance, were decreased. These data provide a potential therapeutic strategy for treatment of hepatic steatosis.
resistance, were reduced following MB07811 treatment. Mechanistic differences in the hepatic effects of MB07811 and T3 could not be explained on the basis of liver TR agonism as both MB07811 and T3 induced TR target genes and enzymes, including carnitine palmitoyl transferase-1, a key enzyme controlling mitochondrial FA oxidation. Changes in acyl-carnitine levels were consistent with an increase in FA oxidation following MB07811 and T3 treatment in vivo. However, only T3 induced lipolysis in isolated adipocytes. Conclusion: Synthetic TR agonists, in addition to their potential beneficial cholesterol lowering properties, represent a novel treatment for reducing hepatic steatosis. The mechanism by which synthetic TR agonists, but not T3, reduce hepatic TG levels is likely related to the inability of the synthetic TR agonists to induce adipocyte lipolysis. Without the influx of FA from the periphery, the TR-driven increase in hepatic FA oxidation reduces hepatic lipid content.

1159 HOMOCYSTEINE SUPPLEMENTATION ATTENUATES, RATHER THAN INCREASES, THE UNFOLDED PROTEIN RESPONSE IN A MURINE NUTRITIONAL MODEL OF STEATOHEPATITIS
Anne S. Henkel, Richard M. Green; Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL

Severe hyperhomocysteinemia is often associated with hepatic steatosis, suggesting that homocysteine (Hcy) is involved in the pathogenesis of fatty liver diseases. In vitro studies and rodent models of severe hyperhomocysteinemia demonstrate activation of the unfolded protein response (UPR) [1]. Despite these correlations, a causal relationship between Hcy and the UPR and hepatic steatosis remains unestablished. Thus, we investigated the effects of Hcy supplementation on hepatic steatosis and activation of the UPR in normal mice and mice fed a methionine-choline deficient (MCD) diet. Methods: FVB/NJ mice (10 wks) were fed either: 1) control (CON); 2) HCY [1.8g/L in H2O]; 3) MCD; or 4) MCD+Hcy diet for 2 weeks. Serum Hcy, ALT, and hepatic lipid content were analyzed. Expression of hepatic genes (CHOP, BiP, XBP-1s) and proteins (p-eIF2α) involved in the UPR were measured by real-time PCR and Western blotting. Results: Mice fed Hcy developed a 2-fold elevation in serum Hcy level (29±6 vs 14±2 μM in CON, p<0.001) yet did not develop hepatic steatosis, serum ALT elevation, nor activation of the UPR. In contrast, mice fed the MCD diet developed severe hyperhomocysteinemia (103±17 μM, p<0.001) and hepatic steatosis (0.7±0.2 vs 0.22±0.06 mg trig/protein in CON, p<0.001). Unexpectedly, the MCD+Hcy group had less ALT elevation (129±30 vs 202±57 IU/L, p=0.01), and gained, rather than lost weight (+4±4% vs -15±1% bw, p<0.001) compared to the MCD group. The MCD diet increased hepatic cholesterol content (48±8 vs 26±3 μg chol/mg protein in CON, p<0.001) and increased hepatic HMG-CoAR expression (1.6-fold vs CON, p=0.02), which did not occur in the MCD+Hcy group. The MCD diet induced 1.3-, 4.8-, 2.4-, and >10-fold increases in expression of CHOP, BiP, XBP-1s and p-eIF2α, compared to CON, respectively (p<0.05). All of these effects were attenuated in the MCD+Hcy-fed mice, (p<0.05) except for BiP expression, which remained upregulated in this group. Hcy alone had no effect on any of the UPR activation pathways compared to CON. Conclusions: Homocysteine supplementation increases serum Hcy 2-fold, but does not cause hepatic steatosis, serum ALT elevation, nor activation of the UPR. The MCD diet causes 10-fold elevations in serum Hcy, significant hepatic steatosis, and UPR activation. Unexpectedly, Hcy supplementation attenuates the deleterious effects of the MCD diet including weight loss, serum ALT elevations, hepatic cholesterol accumulation, and activation of the UPR. This suggests that although hyperhomocysteinemia is often associated with UPR activation and hepatic steatosis, these effects may be a secondary response rather than a direct effect.

1160 GENETIC EVIDENCE THAT LIPID TRAFFICKING PLAYS A KEY ROLE IN FIBROSIS IN NON ALCOHOLIC FATTY LIVER DISEASE
Nimanthu M. De Alwis1, Ann K. Daly1, Guruprasad P. Athaiha2, Elisabeth Henderson1, Julian Leathart1, Sushma Saksena1, Tom Shaw1, Christopher P. Day1; 1Liver Group, Institute of Cellular Medicine, University of Newcastle upon Tyne; Newcastle upon Tyne, United Kingdom; 2Liver Unit, Queens Medical Centre, Nottingham, United Kingdom

Studies suggest that susceptibility to non-alcoholic fatty liver disease (NAFLD) is determined in part, by genetic factors. Previous small studies have reported an association between the Val175Met single nucleotide polymorphism (SNP) in the phosphatidylethanolamine N-methyltransferase (PEMT) gene and non-alcoholic steatohepatitis (NASH). The -493G/T SNP in the promoter of the microsomal triglyceride transfer protein (MTP) gene has also been reported to be associated with steatosis and severity of fibrosis in a small cohort of NAFLD patients. PEMT and MTP are involved in hepatic lipid trafficking and now increasingly implicated in the pathogenesis of progressive NAFLD. We therefore sought to replicate these associations in a large cohort of NAFLD patients. In addition, we also looked for associations between NAFLD severity and functional SNP’s in the genes encoding apolipoprotein E (APOE) (E2,E3,E4 alleles) and cholesteryl ester transfer protein (CETP) I405V which are also involved in lipid trafficking. Methods: A cohort of patients with biopsy proven NAFLD (n=395) from the North of England were included. SNPs in the genes for PEMT (n=287), CETP (n=310), MTP (n=296) and APOE (n=395) were determined using PCR-RFLP analysis. Multivariate analysis (MVA) was used to examine the effects of genotype independent of known risk factors for progressive NAFLD (Type 2 diabetes, age and body mass index). NAFLD severity was graded and staged using modified NASH CRN criteria Results: There were no associations observed for the PEMT Val175Met polymorphism and either steatosis or fibrosis severity or the presence of hepatocyte injury (ballooning). The -493G/T MTP SNP was associated with fibrosis severity (% with stage 3/4 fibrosis; GG 29.8% vs T/* 19%; p=0.025, on multivariate analysis (MVA) p=0.068; Odds Ratio [OR] 1.8 [0.96-3.3]). The I405V CETP SNP was also associated with fibrosis (% stage 3/4; I/I 32.4% vs V*/ V* 18.2%; p=0.003, on MVA p=0.013, OR 2.2[1.2-4.1] as was the APOE E2 allele (% stage 3/4; E2/* 35.9% vs non-E2 22.6%; p=0.022, on MVA p=0.04, OR 2.17 [1.0-4.5]). Neither the MTP, CETP nor APOE SNPs were associated with either steatosis or ballooning. Conclusion: Functional
SNPs in genes encoding proteins involved in hepatic lipid trafficking, MTP, CETP and APOE, but not PEMT, are associated with advanced fibrosis in NAFLD independently of BMI, age and the presence of diabetes. None were associated with cell injury or steatosis severity. These data further support recent studies dissociating steatosis from the pathogenesis of progressive NAFLD and confirm a key role for hepatic lipid transport in the pathogenesis of advanced disease.

1161 ALTERATIONS IN LYMPHOCYTE LIPID RAFT COMPOSITION AND STRUCTURE VIA BETA GLYCOLIPIDS IS ASSOCIATED WITH AMELIORATION OF NON ALCOHOLIC STEATOHEPATITIS: A NOVEL THERAPEUTIC TARGET FOR NASH
Gadi Lalazar, Ami Ben Ya’acov, Dan M. Livovsky, Ehud Zigmond, Yaron Ilan; Liver Unit, Hadassah Hebrew University Medical Center, Jerusalem, Israel

Lipid rafts are microdomains of dynamic assemblies of cholesterol and sphingolipids which organize the plasma membrane into functional units. Raft microdomains represent sites of accumulation for multiple glycosphingolipids (GPI)-anchored membrane proteins, and for proteins targeted to rafts by binding integral raft proteins. Lipid rafts are considered to be critical for proper compartmentalization of insulin signaling. Leptin-deficient ob/ob mice are an accepted model for NASH. Aim: To determine the effect of distinct beta-glycolipids on lipid rafts and the metabolic syndrome in a murine model of NASH. Methods: Leptin deficient ob/ob mice received daily IP injections of 2.5mg/kg beta-glycosylceramide (GC), beta-lactosylceramide (LC), a 1:1 combination of GC and LC (IGL) or PBS, for 6 weeks. Detergent-insoluble fractionation by Triton X-100, was used for studying hepatocytes membranes. Soluble and insoluble fractions extracted from liver were assessed by western blot analysis for ESA-2 (Flotillin-2). The Effect of glycolipids on the metabolic syndrome and on liver damage was assessed by glucose tolerance test (GTT), hepatic fat content (oil-red-O staining), liver enzymes and TUNEL assay. Results: Administration of beta-glycolipids induced alteration of the hepatic detergent-insoluble/soluble fractionation and led to increased expression of ESA-2 in both the soluble and insoluble fractions. Administration of GC and IGL significantly improved the glucose tolerance of Ob/Ob mice (459 and 454 vs. 163 and 190 mg/dl at 30 minutes; 116 and 131 vs. 69 and 71 mg/dl at 180 minutes for PBS and LC vs. GC and IGL respectively; P < 0.01 for GC and IGL vs. PBS). Insulin serum levels were significantly lower in GC group, (128±34 vs. 228 pg/ml for GC vs. PBS, respectively, P = 0.05). IGL administration produced a trend in reduction of total serum cholesterol and triglycerides (5.7 ± 6.18 mmol/L cholesterol for IGL vs. PBS, respectively). Liver weight was lower in all beta-glycolipid treated groups (4.13, 4.38 and 4.38 vs. 4.43 gr, for GC, LC and IGL vs. PBS). The oil-red-O staining of liver biopsies showed a microvesicular fat pattern in beta-glycolipid treated animals and a macrovesicular fat pattern in PBS treated ones. Conclusions: Alteration of cell membranes may provide a new mechanism for understanding the pathophysiology of NASH. Administration of naturally occurring beta glycolipids alters hepatocyte membranes and affects the intracellular signaling machinery, providing a novel therapeutic approach to NASH.

1162 HIGH FAT DIET CHANGES EXPRESSION OF IRON RELATED MOLECULES IN MICE LIVER AND DUODENUM
Shigeki Miyashi, Takaaki Ohtake, Masami Abe, Yasuaki Suzuki, Masumi Ohhira, Yutaka Kohgo; Department of Medicine, Asahikawa Medical College, Asahikawa, Japan

Mild or moderate excess iron is frequently accumulated in liver tissue with non-alcoholic steatohepatitis (NASH) and contributes to liver injury through production of free radical. However the mechanism of iron overload in NASH is still unknown. In this study, we evaluated the iron status in the mouse fatty liver model with high fat diet. Furthermore we investigate expression of iron related molecules in liver and duodenum tissue in this mouse fatty liver model. [Methods] C57Bl/6 mice were fed with control or high fat diet. Mice in each diet were sacrificed after 2, 4, 8, or 16 weeks. Serum alanine aminotransferase (ALT), iron (S-Fe), unsaturated iron binding capacity (UIBC), ferritin were measured and histopathologic evaluation (hematoxylin-eosin stain) were performed. The expression of mouse transferrin receptor 1 (TR1) and hepcidin-1 (Hepc) in the liver and divalent metal transporter 1 (DMT1) in the duodenum were evaluated in these mice model by quantitative real-time RT-PCR method. The protein expression of Hepc and lipid peroxidation product 4-hydroxy-2-nonenal (HNE) as a consequence of oxidative stress were evaluated by immunohistochemical analyses. [Results] Serum ALT and ferritin with high fat diet were higher than those of control after 16 weeks (serum ALT with control or high fat diet; 34 ± 14, 180 ± 65 IU/L, S-Fe; 127 ± 10, 150 ± 34 µg/dl, UIBC; 210 ± 16, 239 ± 39 µg/dl, ferritin; 315 ± 59, 369 ± 37 ng/ml, respectively). The expression of TR1 mRNA in the mice liver with high fat diet was significantly higher than the control diet after 2, 4, 8 and 16 weeks (p<0.05). Hepc mRNA expression in the mice liver with high fat diet was no difference from control diet after 2 and 4 weeks. However Hepc mRNA expression with high fat diet was significantly lower than control after 8 and 16 weeks (p = 0.01). Furthermore the expression of Hepc in the liver with high fat diet was decreased than control. Corresponding to it, DMT-1 mRNA expression with high fat diet was significantly higher than control after 8 and 16 weeks (p = 0.02). The expression of HNE in the liver with high fat diet was induced than control after 16 weeks. [Conclusions] The expression of TR1 mRNA in the mice liver with high fat diet was induced. In addition, the expression of Hepc was decreased and the expression of duodenal DMT1 was increased with high fat diet after 8 and 16 weeks. Our data suggests that fatty liver with high fat diet might up-regulate TR1 expression and down-regulate Hepc expression, following the increased iron uptake into hepatocytes and iron absorption from small intestine.

1163 THE CAR AGONIST, TCPOBOP, ATTENUATES STEATOHEPATITIS IN THE MCD-FED MOUSE
Edwina S. Barkin-Bey, A. Anan, H. Isomoto, S. F. Bronk, Gregory J. Gores; Mayo Clinic College of Medicine, Rochester, MN

Nonalcoholic steatohepatitis (NASH) is a progressive disease in a subset of patients with limited therapeutic options. NASH
is characterized by toxicity from the endobiotic, free fatty acids, and apoptosis. Recently, the constitutive androstane receptor (CAR) has been reported to effect both hepatic detoxification of endo- and xenobiotic pathways and cytoprotection against apoptosis. Thus the AIM of this study was to ascertain whether CAR activation by TCPOBOP modulates steatohepatitis in the methionine choline deficient (MCD)-fed animal. METHODS: C57/BL6 wild type mice (n = 5) were fed either the MCD or CHOW diet for 2 weeks and were treated with vehicle (corn oil), or the CAR agonist, TCPOBOP ((3mg/kg) daily for the first 3 days at the start of week one of the MCD diet), or the CAR inhibitor, androstanol ((100mg/kg) daily for 3 days at the start of weeks one and two of the MCD diet). Gene expression was determined by RT-PCR. Hepatic steatosis was assessed by H&E and digital image analysis. Liver cell apoptosis and inflammation were assessed by TUNEL assay, immunohistochemistry for active caspase 3/7 and CD68 (Kupffer cell marker). RESULTS: mRNA expression of CYP2B10 and CYP3a11, known CAR target genes were increased 45-50-fold in TCPOBOP-treated mice fed the MCD diet (p<0.001), this phenomenon was abated by treatment with the CAR inhibitor, androstanol. Thus CAR can be activated in this animal model of NASH. TCPOBOP treated MCD-fed mice had 25% less hepatic macrosvesicular fat when compared to vehicle-treated MCD-fed mice, p<0.001. In contrast, MCD-fed mice treated with androstanol had 15% more hepatic steatosis as compared to vehicle, p<0.01. Similarly, serum triglyceride levels in MCD-fed mice treated with TCPOBOP were reduced compared to vehicle-treated and androstanol-treated mice, p<0.03. This reduction in hepatic steatosis was accompanied by an increase in enzymes involved in fatty acid microsomal β-oxidation and peroxisomal β-oxidation, namely CYP4A10 (p<0.01), LPBE (p<0.001), and 3-ketoacyl-CoA thiolase (p<0.04) in TCPOBOP treated compared to vehicle-treated MCD-fed mice. Finally, the reduction in steatosis was also accompanied by a reduction in liver cell apoptosis and inflammation. The percent/field area of TUNEL (p<0.01) and caspase 3/7 positive cells (p<0.03) were significantly higher in vehicle-treated MCD-fed mice than TCPOBOP. Immunoreactivity for CD68 was significantly reduced in TCPOBOP treated MCD-fed mice compared with vehicle and androstanol-treated animals, p<0.002. In CONCLUSION: CAR activation can stimulate a unique induction of genes involved in fatty acid oxidation, ameliorating hepatic steatosis, apoptosis and inflammation.

1164 ROLE OF VISCERAL FAT REMOVAL IN THE PREVENTION OF HEPATIC INSULIN RESISTANCE AND TRIGLYCERIDE ACCUMULATION IN RESPONSE TO HIGH FAT DIET IN VIVO

Sigal Fishman1,2, Radhika H. Muzumdar2, Francine H. Einstein2, Gil Atzmon2, Nir Barzilai2; 1Department of gastroenterology and hepatology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; 2Institute for Aging Research and Diabetes Research, Albert Einstein College of Medicine, Bronx, NY

Background: Visceral fat (VF) is associated with the metabolic syndrome and insulin resistance. Therefore, we reasoned that VF accretion might be important in the pathogenesis of non alcoholic fatty liver disease. Aim: The aim of the present study was to determine if surgical removal of VF could prevent hepatic triglyceride (TG) accumulation and insulin resistance induced by short term high fat diet (HFD). Methods: Four groups of 5 young rats were studied: Two groups that preemptively underwent surgical VF removal (VF-) and were fed with either 30% HFD for three days or regular chow (RC). These were compared with 2 groups of age-matched sham operated rats (SO), either with HFD or RC. All visible perinephic and epididymal fat was removed in the VF- groups (~ 2.5 g). Insulin sensitivity was measured by hyperinsulinemic euglycemic clamp (3uU/kg/min) 2 weeks following VF-. Results: Body weight and basal hepatic glucose production (HGP) of the four groups were comparable (13.13.5 mg/kg/min). In SO, HFD significantly decreased insulin-induced suppression of HGP (i.e. hepatic insulin sensitivity) compared to RC (10.7 vs. 6.7 mg/kg/min p<0.01). Preemptive VF- restored HGP under HFD to the level of SO with RC (HGP=7.2mg/kg/min). In accordance with the clamp results, short term HFD significantly increased hepatic TG in SO, while preemptive VF- maintained hepatic TG under HFD (fig 1). During clamping in SO, HFD abolished insulin suppression of plasma free fatty acid (FFA) levels (0.73 meq/l), compared to 0.42 meq/l in RC (p<0.01). However, VF- in HFD group did not improve the ability of insulin to suppress FFA plasma levels (FFA=0.75 meq/l). Conclusion: This study underlines the significance role of VF in the pathogenesis of hepatic insulin resistance and TG accumulation. Moreover, the mechanism by which VF affects the liver does not necessarily involve modulation in FFA delivery.

1165 RESOLUTION OF HEPATIC STEATOSIS DESPITE PERSISTENT OBESITY IN MICE FED STANDARD RODENT CHOW AFTER INDUCTION OF TYPE 2 NAFLD USING THE AMERICAN DIET INDUCED OBESITY SYNDROME MODEL

Brent A. Neuschwander-Tetri1,3, Metin Basaranogl1, Lisa M. Yerian4, Laura H. Tetri1, Elizabeth M. Brun1,2; 1Division of Gastroenterology and Hepatology, Saint Louis University, St. Louis, MO; 2Dept of Pathology, Saint Louis University, St. Louis, MO; 3Saint Louis University Liver Center, Saint Louis University, St. Louis, MO; 4Dept of Pathology, Cleveland Clinic, Cleveland, OH

A recently described model of rapidly progressive severe type 2 NAFLD in mice with obesity and impaired glucose tolerance was developed by combining the major components of diet and lifestyle observed in patients with NAFLD (high fat content, high trans-fat content, sedentary lifestyle and relevant amounts of high fructose corn syrup in the drinking water) [Gastroenterology 2007;132:A-818]. This intervention was termed the American Diet Induced Obesity Syndrome (ADIOS) model. The aim of the present study was to determine the impact of resuming standard rodent chow on obesity, NAFLD and other metabolic abnormalities in ADIOS mice. Methods: 6 week old male C57/BL6 mice were kept sedentary and fed ad libitum a high fat diet (43% of kcal from fat, 30% of fat as trans-fat) and water
containing high fructose corn syrup equivalent (6 g/kg/d) or standard chow and water for 24 weeks. After 16 weeks of treatment, a group of ADIOS mice (n=10) was crossed over to receive standard rodent chow (13% of kcal from fat) for another 8 weeks and compared to ADIOS mice (n=10) and control mice (n=10). Results: Mice crossed over to control chow at 16 weeks remained obese at 24 weeks (see table). Plasma leptin and resistin levels remained elevated in crossover mice, consistent with adipokine production from adipose tissue. Energy consumption was similar among the treatment groups. Despite these persistent similarities between ADIOS mice and crossover mice, NAFLD markedly improved with reduced liver fat and improved plasma ALT and AST. Plasma cholesterol also improved but plasma triglycerides became elevated in crossover mice. Summary: Feeding mice that have NAFLD a standard diet improved liver histology and liver injury despite persistent obesity and hyperleptinemia. Plasma triglycerides increased during the resolution phase, consistent with increased hepatic export. Conclusions: The type of food consumed had a greater impact on the resolution of NAFLD than the presence of obesity in the ADIOS mouse model.

1166 THE DEVELOPMENT OF NEW DRUG SCREENING SYSTEM USING STEATOHEPATITIS MEDAKA FISH MODEL INDUCED BY HIGH-FAT DIET
Toshihiko Matsumoto, Shuji Terai, Shinya Kuvashiro, Kaichi Fujisawa, Naoki Yamamoto, Yoshihiko Hamamoto, Isao Sakaida

Objective: The Medaka fish (Oryzias latipes) is small aquarium fish, have the advantage of having a short generation time and low costs of purchasing, housing and feeding to perform a large-scale screening of drugs. Here we tried to produce and characterize steatohepatitis caused by feeding of a high-fat diet in Medaka fish and analyzed the effect of Eicosapentaenoic acid (EPA) on steatohepatitis. Material and method: Male 8-weeks old see-through Medaka T5 and orange-red color Medaka Cab were administrated the high-fat diet (HFD) for 12 weeks. The process of alteration of the liver and increasing of abdominal adiposity was monitored by repeated observations from outside of the body in the same living T5. At 4, 8, 12weeks, plasma FBS and ALT level were determined. Then composition of hepatic free fatty acid was measured, and paraffin embedded sections of liver were stained with HE and with Gitter and Sirius red. Next we did DNA-chip analysis. Total RNA was obtained from liver each group (Group1:control, Group2:HFD4w, Group3:HFD8w, n=3) and the RNA was analyzed with DNA-Chip system (NANDEMO ARRAY, Gene Frontier). Next Cab were administrated HFD or HFD+10%EPA for 2weeks. The histological change, plasma ALT level and fatty acid composition of hepatic triglycerides were assessed to evaluate the efficacy of EPA. Result: HFD induced medaka fish into obesity, increased abdominal adiposity, fasting hyperglycemia (control:57±21, HFD8w:196±42, mg/dl, p<0.05), and showed severe hepatic steatosis. HFD model showed steatohepatitis by inflammatory infiltrate, sinusoidal fibrosis accompanying with elevation of plasma ALT levels (control:123±42, HFD8w:488±64 IU/L, p<0.05). HFD feeding provoked a 2.4-fold increase of oleic acid and one-tenth decrease of n-3 polyunsaturated fatty acid (PUFA) including Docosahexaenoic acid (DHA) and EPA in the liver. We compared the gene expression profiles among control, HFD4w, HFD8w group using DNA-chip. We found that 2470 genes, including fatty acid binding protein (FABP), phosphoenolpyruvate carboxykinase (PEPCK), α2 type1 collagen, tissue inhibitor of metalloproteinase 2 (TIMP-2) were detected as differentially expressed genes among the three groups. In this model, EPA improved plasma ALT level, hepatic steatosis and inflammatory infiltrate. Then the ratio of the n-3 PUFA to total free fatty acids in the liver was increased. Conclusion: We succeed to develop a new non-alcoholic steatohepatitis model and drug screening system using Medaka fish. EPA will be one of the candidate drugs for hepatic steatosis and steatohepatitis.

1167 HYPOXIA WORSENS NON-ALCOHOLIC STEATOHEPATITIS
Piquet Anne-Christine, Monika Ledermann, Arthur Zimmermann, Deborah Stroka, Jean-Francois Dufour

Background/Aim. Patients with obstructive sleep apnoea syndrome are predisposed to non-alcoholic steatohepatitis (NASH) and insulin resistance. It is unclear whether cellular hypoxia plays a direct pathogenetic role along with the metabolic disorders that are frequently associated with obesity. Conditional knockout mice lacking hepatocellular expression of PTEN develop spontaneously a steatohepatitis (Horie et al., JCI 2004). To investigate the effect of hypoxia on NASH we studied the influence of hypoxia on the development of steatohepatitis in hepatocyte-specific PTEN-deficient mice. Methods. 8 weeks old female hepatocyte-specific PTEN-deficient mice were exposed to a 10% O2 (hypoxic) atmosphere or to 21% O2 (control) atmosphere. Food intake was matched in both groups. After 7 days, mice were euthanized and livers analysed by histology (H&E and Oil red O). NASH lesions were graded according to Kleiner (Hepatology, 2005). Hematocrit, liver morphology (H&E and Oil red O). NASH lesions were graded according to Kleiner (Hepatology, 2005). Hematocrit, liver test, glucose, triglycerides and insulin tolerance were determined in blood. Genes expression of SREBP-1, FOXO1, PPARy, CYP2E1 and hepcidin in the liver were determined by TaqMan. Means±standard deviations, Mann-Whitney test. Results. As
expected the hematocrit level increased in hypoxic mice 61±3% [n=15] compared to controls 49±2% [n=15] (p<0.01). The ratio liver weight/body weight was also increased in the hypoxic animals (4.7±0.3% vs 5.4±0.2% p<0.01). Steatosis was significantly more pronounced in hypoxic mice (2.4±0.8 vs 1.9±0.6, p<0.05) as well as the NAS score (5.2±1.7 vs 2.8±1.4, p<0.01) and the total score (7.7±3.2 vs 3.5±2.5, p<0.01). Oil red O-staining revealed that lipid droplets were more abundant and significantly larger in hypoxic livers. AST (105±25 IU/L vs 70±17, p<0.01) was higher in hypoxic ani- mals as well as triglycerides (1.8±0.4 mmol/l vs 1.1±0.4, p<0.01) and glucose (305±13 mg/dl vs 204±29, p<0.01). Hypoxic mice were more resistant towards insulin than control animals. Expression levels of genes encoding for SREBP1, CYP2E1 and PPARγ were increased by respectively 2.1±0.2, 2.3±0.6 and 4.2±1.9 fold (p<0.05) in liver of hypoxic mice, while hepcidin gene expression was decreased by 5.0±1 fold (p<0.05) and expression of FOXO1 was not affected. Conclusion. This is the first experimental demonstration that hypoxia directly worsens non-alcoholic steatohepatitis. The expression of several genes involved in metabolism was affected by hypoxia in this model. These data suggest that one mechanism is a hypoxia-induced insulin resistance.

1168 DISTINCT REQUIREMENT OF APOB-100 FOR INCREASED SECRETION OF VLDL-TRIGLYCERIDE IN RESPONSE TO HEPATIC OVEREXPRESSION OF MTP IN OB/OB MICE

Zhouji Chen, Elizabeth P. Newberry, Jin Y. Norris, Jianyang Luo, Susan M. Kennedy, Nicholas O. Davidson; Medicine, Washington University School of Medicine, St Louis, MO

Microsomal triglyceride transfer protein (MTP) is a key genetic restriction point in hepatic assembly and secretion of very low density lipoproteins (VLDL). MTP polymorphisms have been linked to variations in plasma lipoprotein levels and non-alco- holic steatohepatitis in patients with type II diabetes and/or obesity. There are distinct requirements for MTP-mediated lipida- tion of apoB isoforms (i.e., apoB48 and apoB100) with apoB100 being exquisitely sensitive to defective MTP expres- sion. We determined the effects of MTP overexpression on hepatic triglyceride (TG) metabolism and VLDL production in the leptin-deficient (ob/ob) mouse and have additionally deter- mined the importance of apoB isoforms in mediating these effects. We crosssed apobec-1/- mice with ob/ob mice to gen- erate an apoB100 only ob/ob mouse (A-ob/ob). These mice, like humans, synthesize and secrete exclusively apoB100-con- taining VLDL from the liver. The obesity phenotype of ob/ob mice of both apobec-1 genotypes was similar, but A-ob/ob mice had increased serum cholesterol levels and higher hepatic TG. A recombinant adenovirus was constructed to express a mouse MTP cDNA (AdmMTP) in vivo and an empty adenovirus expressing GFP alone was used as control. Infusion of AdmMTP elevated hepatic MTP contents 3 fold. MTP overexpression signif- icantly increased hepatic VLDL-TG secretion in A-ob/ob mice but there was no change in ob/ob mice in the wild type apobec-1 background. Hepatic MTP overexpression did not significantly affect hepatic TG contents in any ob/ob genotype. Metabolic labeling studies on primary hepatocytes isolated from A-ob/ob mice demonstrated that MTP overexpression resulted in a 2-fold increase in rates of triglyceride secretion without affecting synthesis and secretion of apoB-100, indicat- ing that MTP overexpression promotes secretion of enlarged VLDL-particles by the liver of A-ob/ob mice. By contrast, over- expression of MTP did not affect hepatic VLDL secretion in the lean apobec-1/- and C57/BL-6 mice. These findings demon- strate that hepatic apoB100 and apoB48 in the lean mice are sufficiently lipidated by endogenous MTP and that there is no gain of function phenotype with MTP supplementation. Taken together, these findings demonstrate that MTP overexpression increases VLDL-TG secretion in ob/ob mice only in the apoB-100 background. Our findings emphasize the importance of apoB genotype in understanding the regulation of hepatic VDL- TG secretion by MTP.

1169 5-LIPoxyGENASE INHIBITION ABROGATES HEPATIC STEATOSIS BY REDUCING LIVER FATTY ACID-BINDING PROTEIN EXPRESSION AND INCREASING HEPATOCYTE MICROsomAL TRIGlycerIDE TRANSFER PROTEIN ACTIVITY

Marta López-Parra1, Esther Titos1, Raquel Horrillo1, Natália Fere1, Marcos Martínez-Clemente1, Ana González-Pérez1, Anna Planagumà1, Jaime Masferrer1, Vicente Arroyo2, Juan Rodes2, Joan Clària1; 1Department of Biochemistry and Molecular Genetics, Hospital Clinic, Centro de Investigación Biomédica Esther Koplowitz (CIBEK), IDIBAPS, University of Barcelona, Barcelona, Spain; 2Liver Unit, Hospital Clinic, Centro de Investigación Bio- médica Esther Koplowitz (CIBEK), IDIBAPS, University of Barcelona, Barcelona, Spain; 3Pfizer, Research and Development, St Louis, MO

The 5-lipoxygenase (5-LO) pathway is an emerging target in obesity, insulin resistance and atherosclerosis. In this study, we explored the possible contribution of this key enzyme of the arachidonate cascade to the progression of hepatic steatosis. The administration of a potent and selective 5-LO inhibitor to leptin deficient mice (ob/ob mice), an experimental model of non-alcoholic fatty liver and steatohepatitis, significantly abro- gated hepatic steatosis as revealed by reduced oil red-O stain- ing and decreased hepatic triglyceride (TAG) content. In these animals, 5-LO inhibition down-regulated liver fatty acid-binding protein (L-FABP) expression while increasing microsomal TAG transfer protein (MTP) activity. No changes in the expression of lipogenic genes and transcription factors such as fatty acid synthase (FAS) and sterol response element-binding protein-1c (SREBP-1c) were observed. The anti-steatotic actions exerted by pharmaco- logical 5-LO blockade were further confirmed by genetic inhibition of this pathway. As compared to wild-type, mice deficient for the 5-LO gene showed reduced susceptibility to develop hepatic steatosis when submitted to a lipoperoxida- tive-induced model of liver injury. Interestingly, analysis of hepatic gene expression by microarrays revealed that a num- ber of genes involved in lipid metabolism including CCAAT/enhancer binding protein beta (C/EBP), car- boxylesterase 3, stearoyl-CoA desaturase 2 (Scd2), ATP-citrate lyase (Acly) and elongation of very long-chain fatty acids 3 and 6 (Elov3 and Elov6), were differentially expressed in 5-LO deficient mice. Consistent with in vivo findings, studies per- formed in cultured murine hepatocytes demonstrated that 5-LO- derived products (i.e. leukotriene [LT] B4 and LTD4) triggered TAG accumulation in the cytosolic compartment, while decreasing extracellular TAG levels. These effects were apparently not mediated by binding to cell surface receptors since neither CP-105,696, a selective LTB1 receptor antagonist, nor MK571, a
selective Cys-LT1 receptor antagonist, were able to prevent LTB4 and LTD4-induced intracellular TAG accumulation. Moreover, both LTB4 and LTD4 significantly reduced MTP activity in hepatocytes without affecting the expression of lipogenic factors (i.e. FAS and SREBP-1c). Taken together, these findings strongly support the concept that the 5-LO pathway participates in the pathogenesis of hepatic steatosis, probably by regulating fatty acid uptake and TAG export in hepatocytes.

1170 DAILY EXERCISE INCREASES HEPATIC FATTY ACID OXIDATION AND PREVENTS STEATOSIS IN OTSUKA LONG-EVANS TOKUSHIMA FATTY (OLETF) RATS

R. Scott Rector1, John Thyfault1, R. Tyler Morris2, Matthew Laye3, Sarah J. Borengasser4, Frank Booth5, Jamal A. Ibdah1; 1Gastroenterology, University of Missouri School of Medicine, Columbia, MO; 2Research, Harry S. Truman Veteran's Medical Center, Columbia, MO; 3Nutritional Science, University of Missouri-Columbia, Columbia, MO; 4Biomedical Sciences, University of Missouri-Columbia, Columbia, MO; 5Medical Pharmacology and Physiology, University of Missouri-Columbia, Columbia, MO

Background: The most common prescribed therapy for individuals with non-alcoholic fatty liver disease (NAFLD) is exercise training and weight loss; however, the effect of daily exercise training upon development of NAFLD in an obese model has not been prospectively examined. This study sought to determine whether exercise training prevents hepatic fatty acid accumulation and the development of NAFLD in Otsuka Long-Evans Tokushima Fatty (OLETF) rats and to elucidate the molecular mechanisms underlying the effect of exercise on hepatic steatosis.

Methods: Four-week old male OLETF rats were randomly assigned to either a sedentary control group (SED, n=8) or were given access to voluntary running wheels for 6 weeks (EX, n=8). Running wheels were locked two days before sacrifice in the EX animals, and both groups were sacrificed at 26 weeks of age. Liver morphology, hepatic triglycerides, fatty acid oxidation, and expression of key proteins involved in fatty acid metabolism were assessed in SED and EX animals. Results: Voluntary wheel running significantly attenuated weight gain and significantly reduced blood glucose, insulin, free fatty acids, and triglycerides in EX animals compared with SED controls (p<0.001). In addition, EX animals exhibited significantly reduced hepatic triglyceride levels compared with SED controls [1.62 ± 0.42 nmol/g (mean ± SE) vs. 2.94 ± 0.61, respectively, P<0.01]. A further analysis of hepatic triglycerides by Oil-Red O revealed that EX animals displayed fewer lipid droplets and reduced lipid droplet size compared to SED animals. Wheel running increased by 3-fold the percent of palmito-lipid droplets and reduced lipid droplet size compared to SED animals.

Conclusion: These results unequivocally demonstrate that daily physical activity attenuates hepatic steatosis and NAFLD in an obese rodent model through enhancement of hepatic fatty acid oxidation and reduction in key protein intermediates of fatty acid synthesis.

1171 PHYLANTHUS URINARIA AMELIORATES THE SEVERITY OF NUTRITIONAL STEATOHEPATITIS

Bo Shen, Jun Yu, Shiyian Wang, Eagle SH Chu, Vincent WS Wong, Xin Zhou, Ge Lin, Joseph JT Sung, Henry LY Chan; The Chinese University of Hong Kong, Hong Kong, China

Aims: Hepatic oxidative stress plays a critical role in the pathogenesis of non-alcoholic steatohepatitis (NASH). Phyllanthus Urinaria (Phyllanthus), a herbal medicine, has been reported to have potential anti-oxidant and anti-inflammation property. We tested the effects of Phyllanthus and the mechanisms of its action on metabolic forms of steatohepatitis both in vitro and in vivo.

Methods: AML-12 hepatocytes were exposed to the methionine and choline deficient (MCD) culture medium and the control medium in the presence or absence of Phyllanthus for 24 hours. Hepatocyte triglyceride, release of alanine aminotransferase (ALT) and lipoperoxides levels were determined. Mice were fed with control or MCD diet for 10 days with or without Phyllanthus (500, 1000 and 2000 ppm). The lowest dosage of Phyllanthus was the equivalent to the recommended dosage used in human. Hepatic steatosis, necroinflammation, triglycerides and lipid peroxide levels were determined. Hepatic expression of inflammatory factors and lipid regulatory mediators were assayed. Results: Phyllanthus significantly reduced steatosis and ALT levels in AML-12 hepatocytes in a dose-dependent manner in vitro. In addition, Phyllanthus prevented MCD-induced hepatic fat accumulation and necroinflammation in mice. This effect was associated with a repressed levels of hepatic lipid peroxides (12.3±7.5 μM/g liver vs 29.7±12.7, P<0.01) as determined by thiobarbituric acid reactive substances assay, reduced expression of cytochrome P450 2E1 (2.5 ± 0.6 vs 4.6 ± 0.14, P<0.05), pro-inflammatory tumor necrosis factor-alpha (1.1 ± 0.8 vs 5.7 ± 4.4, P<0.01), interleukin-6 (1.6 ± 1.1 vs 12.4 ± 7.8, P<0.01) and increased expression of Cyp4a10 (4.1±1.0 vs 1.2 ± 0.6, P<0.05). Hepatic acyl coenzyme A oxidase that regulated hepatic beta-oxidation of fatty acid and other lipid regulators including proliferator-activated receptor gamma (PPARγ), PPARα, CYP2E1, CYP4A14, long-chain acyl-CoA dehydrogenase, stearoyl coenzyme A desaturase-1, liver X receptors-alpha (LXRα), LXRβ, fatty acid synthase, were not affected by Phyllanthus. Conclusions: Phyllanthus clearly attenuated the liver injury of steatohepatitis in cultured hepatocytes and in MCD diet-fed mice in vivo. The mechanisms that Phyllanthus ameliorated steatohepatitis could be attributed to its antioxidant properties via suppression of CYP2E1, anti-inflammatory effects by down-regulating critical inflammatory mediators TNFα and IL-6, and induction of fatty acid oxidation through up-regulation of CYP4A10.

OXIDATIVE STRESS-RELATED DAMAGE IS IMPlicated IN LPS-INDUCED ACTIVATION OF HEPATIC STELLATE CELLS
Paola Brun1,2, Melania Scarpa1,2, Alessia Grillo1,2, Federica Ditadi2, Giorgio Palò2, Diego Martines1, Ignazio Castagliuolo2; 1Surgical and Gastroenterological Sciences, University of Padova, Padova, Italy; 2of Histology, Microbiology and Medical Biotechnologies, University of Padua, Padova, Italy
In the progression of fatty liver to steatohepatitis a key role is played by mitochondrial β-oxidation impairment and disruption of the respiratory chain leading to reactive oxygen species (ROS) production. We previously reported that altered gut mucusal barrier function is associated to increased portal endotoxemia leading to fibrogenic activation of hepatic stellate cells (HSCs). Since oxidative damage is implicated in lipopolysaccharide (LPS) induced-liver injury, we tested the hypothesis that bacterial endotoxins may cause mitochondrial dysfunction and increase ROS formation in cultured HSCs. Low passage murine HSCs were exposed to LPS 10µg/ml with or without 30 min pre-treatment with antioxidant agents: glutathione (GSH, 200µm) and vitamin E (vitE, 500µM). Mitochondrial DNA (mtDNA) damage was assessed by quantitative real-time PCR whereas ROS production and mitochondrial membrane potential (MMP) were determined by flow cytometry analysis using respectively dichlorodihydrofluorescein diacetate fluorophore and tetramethylrhodamine methylester. Redistribution of mitochondrial proteins were studied by Western blot analysis performed on sub-mitochondrial fractions. LPS exposure induced a rapid (within 8 hrs) mtDNA deletion involving the coding regions for NADH dehydrogenase ND1 (0.6±0.15 fold decrease over control, p<0.05) and ND2 (0.4±0.2 fold decrease over control, p<0.05). Deletion of cytochrome c oxidase gene became evident only following 24 hrs of LPS incubation (0.38±0.13 fold decrease over control, p<0.05). LPS-exposed HSCs showed a disrupted MMP within 30 min and an increased ROS production within 75 min. However, HSCs pretreatment with vitE or GSH significantly reduced ROS accumulation and prevented mtDNA deletion. Moreover, LPS exposure induced in HSCs an altered expression of mitochondrial proteins, since Bax was cleaved from the mitochondrial membrane but the translocation to mitochondrial matrix was prevented by GSH treatment. LPS stimulation did not induce a significant mtDNA damage in HSCs isolated from TLR4/-/- mice. Our results indicate that LPS in murine HSCs induces alterations of the mitochondrial machinery such as decreased expression of the complexes I and IV genes, disrupted MMP and redistribution of the mitochondrial protein. We suggest that in the fatty liver LPS-induced ROS production may contribute together with the impaired mitochondrial β-oxidation to establish the oxidative stress responsible for the clinical progression of liver damage.

PIOGLITAZONE RESTORES REGENERATION FAILURE FOLLOWING PARTIAL HEPATECTOMY IN OBSE and DIABETIC KK-Ay MICE
Tomonori Aoyama, Kenichi Ikejima, Kazzuyoshi Kon, Kyoko Okumura, Kumiko Arai, Sumio Watanabe; Department of Gastroenterology, Juntendo University, Tokyo, Japan
Pathogenesis of metabolic syndrome-related NASH in part involves abnormal tissue-repairing responses in the liver. Although poor hepatic regeneration has been demonstrated in a variety of experimental models of hepatic steatosis/steatohepatitis, no effective therapeutic approach has been established yet. In this study, we investigated whether pioglitazone, a thiazolidinedione derivative (TZD), improves hepatic regenerative responses in obese, diabetic KK-Ay mice. Methods: Male KK-Ay and C57Bl/6 mice 12 weeks after birth underwent 2/3 partial hepatectomy (PH). Some mice were given repeated intragastric injection of pioglitazone (25 mg/kg) for 5 days prior to operation. Hepatocyte proliferation was evaluated by BrdU uptake, and hepatic expression of cyclin D1 and phosphorylation of STAT-3 were detected by Western blotting. TNF-α and socs-3 mRNA levels in the liver were determined by real-time RT-PCR. Serum IL-6 and adiponectin levels were measured by ELISA. Results: Half number of KK-Ay mice which underwent PH died within 48 hr, whereas this mortality was completely prevented in mice given pioglitazone for 5 consecutive days prior to PH. In KK-Ay mice, BrdU incorporation to hepatocyte nuclei 48 hr after PH was as low as 2%; however, pioglitazone pretreatment increased BrdU-positive cells to 8% (p<0.05), the levels being almost 1/3 of Bl/6 given PH. Cyclin D1 was barely detectable in hepatotomized livers in KK-Ay mice within 48 hr. In contrast, weak, but overt expression of cyclin D1 was observed 24 hr after PH in KK-Ay pretreated with pioglitazone. Hepatic expression of TNF-α mRNA was tremendously increased 1 hr after PH in KK-Ay, the levels reaching 9-fold over Bl/6 given PH. Pretreatment with pioglitazone blunted this increase almost 3/4. Serum IL-6 levels were also elevated extensively 24 hr after PH in KK-Ay mice, while the levels were largely decreased in KK-Ay mice given pioglitazone. Further, aberrant increases in phosphorylation of STAT-3 and socs-3 mRNA in the liver in KK-Ay mice were also tended to be normalized by pioglitazone. Interestingly, hypothalamic neocortex observed in KK-Ay mice was corrected by pioglitazone pretreatment to the levels almost similar to Bl/6 controls. Conclusions: These findings indicated that pioglitazone reverted, in part, poor regenerative responses in the liver in KK-Ay mice. The mechanism underlying the effect of pioglitazone on regeneration failure most likely involves normalization of expression pattern of adipokines and subsequent cytokine responses during the early stage of PH. It is therefore postulated that TZDs prevent progression of NASH in part through restoration of tissue repairing responses in the liver.

MECHANISM OF SERUM ALT INCREASE IN EXPERIMENTAL NASH
Rui Liu, Xiaomin Pan, Peter F. Whitington; Children's Memorial Research Center, Chicago, IL
Purpose: Serum ALT is a biomarker of hepatocyte injury in hepatitis of various etiologies including NASH. Increased activity is thought to be related to increased release from hepatocytes. We sought to understand the mechanisms involved in models of experimental NASH hypothesizing that serum values reflect increased hepatocyte expression rather than hepatocyte injury. Methods: Experimental NASH was produced in female A/J mice by feeding a methionine and choline deficient (MCD) diet versus an identical replete (MCR) diet and by treating mouse AMI-12 hepatocytes in culture with MCD versus MCR medium ± the P13-kinase inhibitor LY294002 (LY). ALT activity was measured enzymatically, expressions of the ALT isoforms ALT1 and ALT2 by Western blot, and abundance of ALT1 and ALT2
mRNA by real-time PCR. Significance of results for MCD v. MCR was determined by t-test: all reported results were significant at p<0.05. Results: Serum ALT activity in mice fed the MCD diet for 12 weeks was 383 ±5.6 U/L v. 92 ± 2.1 for MCR. The expressions of ALT1 and ALT2 protein in serum were proportionately increased; 2-fold and 1.5-fold, respectively. The expressions of ALT1 and ALT2 protein in liver tissue were increased to a degree greater than in serum; 7-fold for ALT1 and 10-fold for ALT2. Hepatic protein expression correlated with mRNA expression: 2-fold increased for ALT1 and 4-fold for ALT2. The medium from 18-hr MCD treated AML-12 cells showed increased ALT activity (81.5 ± 7.8 U/L v. 57.5 ± 0.7), and the cellular ALT activity was proportionately increased (80.1 ± 1.6 U/L/mg protein v. 44.1 ± 1.6). Cellular ALT protein and mRNA expressions were correspondingly increased after treating with MCD medium. The increased medium ALT, cellular ALT activity and cellular ALT1 and ALT2 protein and mRNA expressions were completely eliminated by treating with LY. In all in vivo and in vitro conditions, hepatocyte necrosis and apoptosis were measured to be insignificantly increased. Conclusions: Increased serum and medium ALT activity in these mouse models of experimental NASH correlates closely with the increased hepatocyte expression of ALT protein and not with the degree of hepatocyte death. The increased ALT protein expression in liver/hepatocytes correlates with mRNA expression, suggesting a translational mechanism for increased expression. Increased in vitro ALT release and cellular protein and mRNA expression during MCD treatment is entirely dependent upon activating the PI3-kinase cell survival pathway. These findings suggest increased serum ALT in experimental NASH results from increased hepatic expression with a constant “leak”. The pathway of leak is to be explored.

1175 THE MITOCHONDRIAL SUPEROXIDE DISMUTASE 2 (SOD2) TARGETING SEQUENCE POLYMORPHISM IS ASSOCIATED WITH FIBROTIC NAFLD: CONSISTENT EVIDENCE FROM CASE-CONTROL AND INTRA-FAMILIAL ALLELIC ASSOCIATION STUDIES

V. Nobili², Ann K. Daly¹, A. Al-Serri¹, M. Marcellini², A. Alisi⁰, M. Manco¹, Julian Leathart¹, J. Graham¹, Christopher P. Day¹; ¹Liver Group, Institute of Cellular Medicine, University of Newcastle upon Tyne, Newcastle upon Tyne, United Kingdom; ²Liver Unit, Bambino Gesù Hospital, Rome, Italy

Family studies and studies in different ethnic groups suggest that susceptibility to progressive non-alcoholic fatty liver disease (NAFLD) - non-alcoholic steatohepatitis (NASH) and fibrosis - has a genetic component but the genetic variants underlying this susceptibility remain largely unknown. Studies in both animals and humans suggest that oxidative stress/lipid peroxidation are important in the pathogenesis of fibrosis in NAFLD with mitochondria an important source of reactive oxygen species (ROS). A small study in 63 patients has reported that homozygosity for the T allele, which encodes a valine in the mitochondrial targeting sequence of superoxide dismutase 2 (SOD2), associated with less efficient mitochondrial import, is more common in patients with NASH than in healthy controls. We have used two complementary approaches to examine this mechanistically plausible association. First, we performed a classical case-control allelic association study in a large series of patients with biopsy proven NAFLD to determine if the Ala/Val SOD2 single nucleotide polymorphism (SNP) is associated with disease severity. Second, we performed an intra-familial association study in “trios”, with an index child with fibrotic NAFLD and two surviving parents, to look for preferential transmission of either SOD2 allele to the affected child using transmission disequilibrium testing (TDT). This approach is not subject to the potential confounding effects inherent in case-control studies and is significantly more powerful at detecting true associations. Methods: In the case control study, 282 adult patients with biopsy-proven NAFLD were genotyped for the Ala/Val SOD2 SNP and associations were sought with the severity of fibrosis and the presence of hepatocyte ballooning using the NIH NASH CRN staging system for fibrosis. In the family study 71 trios with an index child with fibrotic NAFLD were genotyped for the SOD2 SNP and the TDT was applied. Results: In the case control study the presence of significant fibrosis (stage >1) increased with the number of Val (T) alleles; Ala/Ala 23%, Ala/Val 37%, Val/Val 45%, p=0.034. There was no association with hepatocyte ballooning. In the family study 55 families were “informative” in that one or both parents were heterozygous for the SNP. In these families the Val allele was transmitted on 47/76 (62%) possible occasions whereas the C allele was transmitted on only 29/76 (38%) occasions, p=0.038.

1176 STUDY OF THE MITOCHONDRIAL COMPLEX I BY BLUE NATIVE ELECTROPHORESIS IN LEAN AND OB/OB MICE

Inmaculada García-Ruiz², Cristina Rodriguez-Juan², Teresa Díaz Sanjuán², Daniel Fernández-Moreira², Mercedes Pérez-Carreras¹, Teresa Muñoz-Yagüe¹, Jose A. Solis-Herruzo¹,2; ¹Liver Mitochondria and Mitochondrial Dysfunction Research Unit, Hospital Universitario “12 de Octubre”, Madrid, Spain; 2Research Center, Hospital Universitario “12 de Octubre”, Madrid, Spain

In previous studies we have shown that the activity of the mitochondrial respiratory chain (MRC) is decreased in patients with nonalcoholic steatohepatitis and in ob/ob mice. Moreover, treatment of ob/ob mice with rosiglitazone (RGZ) reduces the activity of complex I of the MRC. Mechanisms leading to this dysfunction are not known. The aims of this study were to determine the integrity state of mitochondrial complex I in normal and ob/ob mice and the effect of RGZ on this complex. Methods: In liver samples from normal and ob/ob mice as well as in liver from both type of animals treated with 1 mg/Kg/day RGZ for 12 weeks we measured: (1) activity of complex I by in-gel activity assay, (2) the level of fully assembled complex I in a BN-PAGE system, blotted, and incubated with antibody against subunit p39, (3) complex I assembly by second dimension SDS-PAGE, blotted, and incubate with antibodies against complex I subunit p39, p30 and p20. Results: (1) In-gel activity assay confirmed that activity of complex I was almost absent in the liver of the ob/ob mice and that RGZ treatment decreased markedly the activity of this complex in normal mice. (2) Complex I remained fully-assembled in RGZ-treated mice, but was completely unassembled in ob/ob mice. (3) Second dimension SDS-PAGE system demonstrated that levels of fully-assembled complex I was increased in RGZ-treated animals, while assembly of complex I was severely affected in ob/ob mice. Conclusion: This study demonstrates that the activity of complex I is markedly decreased in RGZ-treated and ob/ob mice, but, while in RGZ-treated animals it is likely due to a catalytic defect, in ob/ob mice it is due to a defect in the assembly process.

TRB3 IS ASSOCIATED WITH HEPATIC LIPOGENESIS AND DYSLIPIDEMIA IN NAFLD
Luca Valentì,1 Raffaela Rametta1, Paola Dongiovanni1, Anna Ludovica Fracanzani1, Giancarlo Roviaro2, Silvia Fargion1; 1Internal Medicine, University of Milan, Ospedale Policlinico IRCCS, Milano, Italy; 2Surgery, University of Milan, Ospedale Policlinico Mangiagalli Regina Elena IRCCS, Milano, Italy

Background & Aims: The AKT kinase mediates the insulin drive on lipogenesis in hepatocytes by inducing the transcription factor SREBP-1. The Drosophila Tribbles homolog TRB3 has been reported to inhibit AKT activity and lipogenesis in animal models of insulin resistance, and to promote ubiquitination and degradation of acetyl-coenzyme A carboxylase, rate limiting enzyme in lipid synthesis. Aim was to evaluate TRB3 expression and the correlation with steatosis and dyslipidemia in patients with NAFLD, and evaluate the effect of the functional TRB3 Glu84Arg polymorphism on the metabolic picture. Patients and Methods: Liver biopsies of 20 patients with NAFLD (10 NASH and 10 with simple steatosis according do Kleiner), and 15 without metabolic diseases were considered; gene expression measured by qRT-PCR and Western blotting; the TRB3 Glu84Arg polymorphism evaluated by restriction analysis. Results: TRB3 expression was lower in NASH compared to simple steatosis and controls (p<.05), and was negatively correlated with steatosis percentage, triglycerides/HDL ratio, and HOMA-IR index compared to those with simple steatosis and without metabolic diseases (p<.05). Decreased TRB3 expression was associated with increased lipogenesis and insulin resistance in NAFLD.

TRB3 IS ASSOCIATED WITH HEPATIC LIPOGENESIS AND DYSLIPIDEMIA IN NAFLD

HEPATIC ADIPOR2 SIGNALING REGULATES THE DEVELOPMENT OF NONALCOHOLIC STEATOHEPATITIS IN MICE
Kengo Tomita1, Yuichi Oike4, Terufumi Yokoyama2, Takashi Taguchi1, Shinobu Tanaka3, Masaaki Noguchi2, Toshiaki Teratani1, Takahiro Suzuki1, Hirokazu Yokoyama3, Mitsuhisa Tabata4, Tamiko Okhura2, Toshifumi Hibi1; 1Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan; 2Department of Molecular Genetics, Graduate School of Medical Sciences, Kumamoto University, Kumamoto, Japan

Background and Aims: Decreased expression of AdipoR2 in the livers of patients with NASH has recently been reported, indicating the possibility that adiponectin signaling mediated by AdipoR2 plays an important role in the pathogenesis of NASH. How hepatic adiponectin resistance and sensitivity mediated by its receptor, AdipoR2, contributes to the progression of nonalcoholic steatohepatitis (NASH) is unclear. We examined the roles of hepatic AdipoR2 in NASH using an animal model. Methods: We fed C57BL/6 mice a methionine- and choline-deficient (MCD) diet for up to ten weeks and analyzed changes in liver pathology caused by a mouse AdipoR2 short hairpin RNA-expressing adenovirus, an AdipoR2-overexpressing adenovirus, or an adiponectin-overexpressing adenovirus. Results: Inhibition of hepatic AdipoR2 expression aggravated fatty changes, inflammation and fibrosis in steatohepatitis, increasing lipid peroxidation, and decreasing hepatic glutathione content. It decreased hepatic peroxisome proliferator-activated receptor (PPAR)-α activity and the expression of acyl-CoA oxidase (ACO) and catalase, and increased the expression of proinflammatory cytokines, chemokines, and adhesion molecules. Hepatic AdipoR2 overexpression significantly alleviated steatohepatitis, decreasing lipid peroxidation while increasing hepatic glutathione content, PPAR-α activity, and the expression of ACO and catalase. It reduced the expression of inflammatory cytokines, chemokines, and adhesion molecules. In primary cultures, the expression of AdipoR2 in activated hepatic stellate cells controlled the inhibition of proliferation and the promotion of apoptosis of these cells by adiponectin. Conclusions: Hepatic AdipoR2 signaling regulates steatohepatitis progression by changing PPAR-α activity and reactive oxygen species (ROS) accumulation, making liver AdipoR2 signaling a promising target in treating NASH.

activity in pre-beta HDL, converts HDL from pro- to anti-inflammatory, and enhances endothelial eNOS activity. We have studied D-4F in a mouse model of NASH with significant fibrosis. Methods: C57BL/6J male mice were given 7 months of a Western diet (WD) followed by 2.5 months of: group 1- WD, group 2-WD + D-4F (125 microgram/mouse/day), group 3-chow, group 4- chow + D-4F. Control groups: 6-month-old C57BL/6J mice (normal control), C57BL/6J mice fed WD for 6 months (baseline for fibrosis progression). Steatosis and inflammation were determined by semi-quantitative assessment. Fibrosis was determined by whole-section-scanning morphometry of Sirius red stained slides with correction for staining of large vessels. Results: Group 1 had very marked increases in body weight (40.0 ± 5.2 g), hypercholesterolemia (288.0 ± 5.4 mg/dl), hyperglycemia (270.2 ± 10.0mg/dl), hyperinsulinemia (3.3 ± 3.0 ng/ml), insulin resistance (HOMA-IR 62.8 ± 5.1), and hyperleptinemia (32.6 ± 1.9 ng/ml). Liver weight (2.7 ± 0.7g) was twice that of controls, AST (268 ± 29.6 U/L) and ALT (235.2 ± 23.5 U/L) were 5-12 x elevated, and there was evidence of oxidative stress in the liver with increased tissue TBARS (27.1 ± 4.0 nmol/g tissue) and decreased GSH (39.6 ± 4.8 nmol/mg protein). There was marked steatosis and inflammation, increased alpha-smooth muscle actin staining, and increased fibrosis with 4.6 ± 1.9% of surface area positive for Sirius red staining (compared to 0.1 ± 0.0% for 6 month control mice). In group 2, total cholesterol and leptin levels were decreased by half compared to group 1. There was no improvement in body weight, liver weight, hyperglycemia, hypertriglyceridemia, insulin resistance, or oxidative stress with D-4F. Group 2 showed no improvement in steatosis and a small decrease in inflammation. Nevertheless, D-4F reduced fibrosis from 4.6% in group 1 to 1.3 ± 0.3% in group 2 (p<0.025 group 1 vs 2). 6 month WD (fibrosis baseline): 0.42 ± 0.04% fibrosis. Group 3 and 4 showed comparable improvements in all biochemical measures, albeit no normalization, and comparable improvements in steatosis and inflammation. However fibrosis in group 4 (0.89 ± 0.21%) was significantly less than in group 3 (2.79± 0.66%), p<0.05. Conclusion: C57BL/6J mice given a WD for 9 months develop features of the metabolic syndrome with NASH and fibrosis. In this model, D-4F significantly prevented progression of fibrosis without improving steatohepatitis, oxidative stress, or insulin resistance.

HEPATOCYTE SPECIFIC GP130 PROTECTS AGAINST THE DEVELOPMENT AND PROGRESSION OF STEATOHEPATITIS

Daniela Kroy1, Naiara Beraza1, Uta Dierssen1, Leif Sander1, Werner Plum1, Nikolaus Gassler2, Christian Trautwein1, Konrad L. Streetz2. 1Department of Medicine III, RWTH Aachen, Aachen, Germany; 2Department of pathology, RWTH Aachen, Aachen, Germany

The metabolic syndrome and the related development of hepatic steatosis is a growing medical problem in western industrial countries. Inflammatory processes play an important role in the development of hepatic steatosis progressing to non-alcoholic steatohepatitis (NASH) and ultimately liver fibrosis. The role of pro-inflammatory IL-6-type cytokines in NASH remains unclear. Thus, we aimed to investigate the involvement of gp130, the shared receptor subunit of IL-6 cytokines in liver steatosis and subsequent NASH. For this aim we used hepatocyte-specific conditional gp130 knockout mice (hepaΔgp130). Furthermore we combined conditional knockout and knockin technology to achieve hepatocyte specific deletion of gp130-dependent RAS/Erk (hepaΔgp130RAS) or STAT (hepaΔgp130STAT) activation. Wildtype and knockout mice were fed a cholin-deficient, ethionin supplemented diet (CDE). As early as two weeks after the start of CDE diet, hepaΔgp130 mice exhibited signs of hepatic steatosis confirmed by Oil red and H&E staining, in contrast to their wildtype littermates that displayed no significant phenotype. After four weeks, the effect was even stronger with a higher level of hepatic steatosis in the hepaΔgp130 mice while wildtype mice remained unaffected. Additionally, we observed accumulation of collagen-fibres as initial signs of fibrosis in the hepaΔgp130 group. Metabolic analyses revealed an increased content of liver triglycerides and elevated fasting blood glucose levels in CDE fed hepaΔgp130 mice four weeks after treatment, further corroborating the histological phenotype. Significantly increased TNF-α and decreased adiponectin mRNA levels were found in liver samples of hepaΔgp130 mice compared to wildtype controls, demonstrating the inflammatory response. Moreover, gp130 deficient mice displayed a lethal phenotype after insulin stimulation, further showing the profound impairment of metabolic pathways. In order to identify intracellular signalling pathways, hepaΔgp130STAT and hepaΔgp130RAS mice also received the CDE diet. While no liver pathology was observed in hepaΔgp130RAS, hepaΔgp130STAT exhibited a phenotype similar to the gp130 deleted mice. This clearly demonstrates the central role for STAT3 in gp130 mediated liver protection in this novel model of NASH. We conclude that gp130 exerts important protective effects in the establishment and progression of steatohepatitis and fibrosis and might therefore represent a potential target for therapeutic intervention.

NOVEL THERAPEUTIC APPROACH FOR NAFLD USING ANTIPLATELET AGENTS IN AN ANIMAL MODEL

Koji Fujita, Masato Yoneda, Yuichi Nozaki, Hiroshi Iida, Takuma Higurashi, Hironori Mawatari, Hiroki Endo, Ayako Tomimoto, Kyoko Yoneda, Tomoyuki Akiyama, Hirokazu Takahashi, Ayumu Goto, Satoru Hirokawa, Yasunobu Abe, Masahiko Inamori, Nori-toshi Kobayashi, Hiroyuki Kirikoshi, Kensuke Kubota, Satoru Saito, Atsushi Nakajima; gastroenterology, Yokohama-city university graduate school of medicine, Yokohama, Japan

[BACKGROUND AND AIMS] We found that some NASH patients treated with antiplatelet agents showed a tendency towards decrease in the plasma levels of the transaminases and triglyceride. However, the precise mechanisms underlying the therapeutic efficacy of antiplatelet agents in NASH have not yet been elucidated. Therefore, we investigated the therapeutic effects of antiplatelet agents against NASH in an animal model. [METHODS] Experimental design 1: We used three classes of antiplatelet agents (aspirin, ticlopidine, cilostazol). Three hundred forty-four 6-week-old male Fisher rats were divided into five groups (choline-deficient, l-amino acid defined (CDAA) diet, CDAA diet + aspirin 5mg/kg/day, CDAA diet + ticlopidine 3mg/kg/day, CDAA diet + cilostazol 3mg/kg/day, normal diet) and sacrificed after 16 weeks. Experimental design 2: Three hundred forty-four 6-week-old male Fisher rats were divided into four groups (high-fat high-calorie (HF/HC) diet, HF/HC diet + cilostazol 3mg/kg/day, HF/HC diet + cilostazol 9mg/kg/day, normal diet) and sacrificed after 16 weeks. The serum levels of markers of inflammation, fibrosis, lipid metabo-
lism and glucose metabolism were measured along with high-sensitivity lipoprotein profiling. Liver fibrosis, inflammation and steatosis were quantified by Masson's Trichrome, HE and Oil red staining. Protein and RNA were isolated from various tissues, such as the liver, subcutaneous fat, mesenterial visceral fat and muscle. Protein kinase A, MAP kinase, hepatocyte growth factor (HGF), PDGF were also measured. [RESULTS] All of the antiplatelet agents produced improvement of the steatohepatitis. Especially, cilostazol markedly attenuated the hepatic steato-sis, inflammation and fibrosis in the CDAAM-fed rats as compared with other antiplatelet agents. The quantitative parameters of steatosis, inflammation and fibrosis were also ameliorated by treatment with cilostazol. We further investigated the mechanisms underlying the therapeutic effect of antiplatelet agents against NASH in the HF/HC model. The cilostazol-fed model showed low plasma leptin, low plasma triglyceride and high plasma HDL-cholesterol levels and also improved insulin resistance (p<0.001). Moreover, the cilosta-zol-fed models showed upregulation of protein kinase A and HGF, and downregulation of MAP kinase and PDGF (p<0.001). [CONCLUSION] Antiplatelet agents, as a novel therapeutic candidate for NASH, in particular, cilostazol, a selective cAMP phosphodiesterase inhibitor, produced marked improvement of the steatohepatitis through cAMP activation and PDGF downregulation. Our results open up a novel therapeu-tic lead for the treatment of NASH.

Disclosures: The following people have nothing to disclose: Koji Fujita, Masata Yameda, Yuichi Nazaki, Hiroshi Iida, Takuma Higurashi, Hironori Mawatari, Hiroki Endo, Ayako Tomimoto, Kyoko Yameda, Tomoaki Akiyama, Hirokazu Takahashi, Ayumu Goto, Satoru Saito, Satoru Hirokawa, Yasunobu Abe, Masahiko Inamori, Noritoshi Kobayashi, Hiroyuki Kirikoshi, Kensuke Kubota, Satoru Saito, Atsushi Nakajima

ENDOCANNABINOID PRODUCTION BY MONOCYTES IS INCREASED IN NONALCOHOLIC STEATOHEPATITIS Onpan Cheung1, Carol C. Sargeant1, Vincenzo Di Marzo2, Puneet Puri1, Faridoddin Mirshahi1, Arun J. Sanyal1

The hepatic content of endogenous cannabinoids (EC) is increased in an animal model of diet-induced fatty liver. Monocytes are an important source of EC and also produce many cytokines that affect both metabolism and inflammation. Hepatic macrophages are derived from both circulating monocytes and resident macrophages. There are no data on EC production in human nonalcoholic steatohepatitis (NASH) or their effects on cytokine production by macrophages. SPECIFIC AIMS: (1) To compare EC production by circulating peripheral blood monocytes (PBM) from subjects with NASH to those with the metabolic syndrome but without nonalcoholic fatty liver disease (NAFLD) and lean normal controls. (2) To define the effects of methanandamide (mAEA), an EC, on PBM cytokine production. (3) To determine if PBM derived EC modulate the cytokine response of PBM to their natural activator lipopolysaccharide (LPS). METHODS: PBM from 15 subjects (NASH=5, metabolic syndrome=5, lean normal=5) were isolated on a Histopaque (LPS). METHODS: PBM from 15 subjects (NASH=5, metabolic syndrome=5, lean normal=5) were isolated on a Histopaque column. Anandamide (AEA), palmitoylethanolamide (PEA) and 2-arachidonylglycerol (2AG) production following LPS stimulation was measured by HPLC and results normalized to lipid content. Cytokines (interleukin (IL)-1β, 2, 4, 5, 6, 8, 10, 12p40, 12p70, 13, TNF-α, interferon-γ, IP-10, MIP-1β) produced by PBM were measured by EUSA following exposure to mAEA, LPS and LPS after CB1 and CB2 receptor antagonists (SR141716 and SR144528) pretreatment. RESULTS: Compared to normal controls and those with the metabolic syndrome, subjects with NAFLD produced significantly more AEA (mean values, pmol/mg lipid: 21 vs. 14 vs. 13, p<0.05) and PEA (48 vs. 31 vs. 20, p<0.05). 2AG was not detected. PBM treated with mAEA increased pro-inflammatory cytokines IL-8 (mean values, pg/ml: 1,335 vs. 848, p<0.03) and IL-1β (142 vs. 116, p<0.03) production while decreased that of TNF-α (136 vs. 223, p<0.001) from baseline. It also decreased anti-inflammatory cytokine IL-4 (33 vs. 102, p=ns) production. LPS increased IL-8 (1,380 vs. 762, p<0.03) and decreased IL-4 (18 vs. 116, P<0.002), IP-10 (33 vs. 68, p<0.0001) and IL-6 (1,094 vs. 1,185, p<0.005) production. Only LPS induced increase in IL-8 was abrogated by CB1 and CB2 receptor antagonists pretreatment. CONCLUSIONS: (1) EC production by PBM is significantly increased in NASH. (2) AEA causes a pro-inflammatory profile of cytokine production by PBM by increasing IL-1β and IL-8 while decreasing IL-4. (3) PBM production of IL-8 in response to LPS is mediated by EC acting via CB receptors in an autocrine manner. Disclosures: The following people have nothing to disclose: Onpan Cheung, Carol C. Sargeant, Vincenzo Di Marzo, Puneet Puri, Faridoddin Mirshahi, Arun J. Sanyal

THE TRADITIONAL JAPANESE KAMPO FORMULA KEISHIBUKURYOGAN AMELIORATES STEATOSIS, REDUCES OXIDATIVE STRESS AND INFLAMMATION, AND ULTIMATELY PREVENTS LIVER FIBROSIS IN A RABBIT MODEL OF NON ALCOHOLIC STEATOHEPATITIS Makoto Fujimoto1,2, Koichi Tsuneyama2,3, Masaburo Kainuma4, Nobuyasu Sekiya2, Yasuo Takano5, Katsutoshi Terasawa6,9, Carlo Selmi7,8, M. Eric Gerstwin7, Yukata Shimada1,2,3, Japanese Oriental Medicine, University of Toyama, Toyama, Japan; 4Diagnostic Pathology, University of Toyama, Toyama, Japan; 521st Century COE Program, University of Toyama, Toyama, Japan; 6Environmental Medicine and Infectious Diseases, Kyushu University, Fukuoka, Japan; 7Frontier Japanese Oriental Medicine, Chiba University, Chiba, Japan; 8Japanese Oriental Medicine, Chiba University, Chiba, Japan; 9Internal Medicine, University of California, Davis, Davis, CA; 8Clinical Sciences ‘Luigi Sacco’, University of Milan, Milan, Italy

The mechanisms responsible for the progression of non alco-holic fatty liver disease (NAFLD) to steatohepatitis (NASH) remain unknown although oxidative stress and inflammation appear to play a crucial role. Although traditional Chinese and Japanese medicine has been advocated for a variety of human diseases, the vast majority of such studies lack the appropriate quality controls, standardization, and evidence-based blind evaluation. We have been intrigued with specific Japanese herbal compounds (Kampo formulas) alleged to have significant antioxidant activity. We studied the effects of 12-week supple-ments with three Kampo formulas [keishibukuryogan (1% KBG, TJ-25), orenegokoto (1% OOT, TJ-15) and shoaikoto (1% SST, TJ-9)] or two proposed NASH treatments [i.e. vitamin E (VE) and pioglitazone (PG)] on a cholesterol-fed rabbit model of NAFLD/NASH. Control groups were fed with standard rabbit chow and SRC containing only 1% cholesterol (C). Our readouts included (i) markers of liver function, lipid and glucose metabolism; (ii) liver histology and tissue lipid contents; (iii) oxidative stress; and (iv) plasma mediators of inflamma-tion and fibrosis. Results demonstrate that (i) total cholesterol levels in group C were significantly higher compared to each of the other supplemented groups (P<0.01 for all comparisons) and the KBG group had the lowest total cholesterol levels with the expected exception of the group not receiving cholesterol nor treatments while no significant differences were observed
between treatment groups in fasting glucose, insulin levels, or transaminase activities. (ii) KGB treatment led to significantly lower levels of total cholesterol (P<0.01), free cholesterol (P<0.01), and triglycerides (P<0.05) in the liver tissues. KGB treatment was associated with significantly higher adiponectin levels. (iii) KGB treatment was associated with significantly lower levels of plasma lipid peroxide compared to group C; urinary amounts of 8-OhdG were significantly reduced in all 5 supplement groups. (iv) KGB treatment was characterized by significantly reduced proportions of α-SMA positive areas and hepatic stellate cells at immunohistochemistry. Plasma levels of hyaluronic acid and TGF-β1 were significantly lower in groups KGB, OGT, and VE compared to group C. In conclusion, Kampo formulas (KGB in particular) exert a significant protective effect in a dietary rabbit model of NAFLD/NASH through several mechanisms that ultimately prevent the progression to liver fibrosis. We should also emphasize the rigor of these data and the need not only for further observations but also for the evaluation of cellular and molecular mechanisms.

1184 PALMITATE-INDUCED LIPID ACCUMULATION IN HEPATOCYTES LEADS TO ACTIVATION AND PRO-FIBROTIC GENE EXPRESSION IN HEPATIC STELLATE CELLS – A NEW IN VITRO MODEL TO STUDY FIBROGENESIS IN NAFLD

Hella Wobser1, Christoph Dorn2, Thoams Weiss2, Roland Buettner1, Cornelius Boltlheimer1, Juergen Schoelmerich1, Claus Hellerbrand1; 1Department of Medicine, University Clinics, Regensburg, Germany; 2Department of Surgery, University Clinic, Regensburg, Germany

Nonalcoholic fatty liver disease (NAFLD) is a frequent and potentially progressive chronic liver disease. A subset of patients with NAFLD develop non-alcoholic steatohepatitis (NASH), hepatic fibrosis and end-stage liver disease. Current evidence indicates that hepatic stellate cells (HSC) play the central mediators of liver fibrosis. The molecular mechanism linking hepatocyte steatosis to activation of HSC, thereby promoting inflammation and fibrosis, are mainly unknown. Here, we demonstrate a novel in vitro model to study the effect of hepatic lipid accumulation on HSC. Methods and Results: After exposure of primary human hepatocytes (PHH) and human hepatoma cells (HUH7) to the saturated fatty acid palmitate (PA), significant intracellular lipid accumulation was documented morphologically and by colorimetric assays. Subsequently, conditioned-media (CM) from PA-treated cells were used for stimulation of human hepatic stellate cells (HSC), leading to a significant induction of Collagen I, TGF-β1, TIMP-1/2 and MCP-1 mRNA and protein expression, as assessed by quantitative PCR and ELISA. Furthermore, CM from PA-treated hepatocytes induced the proliferation and activation process of HSC. Moreover, reporter gene assays revealed a significantly enhanced NFκB activation in HSCs after stimulation with CM from PA-treated hepatocytes as compared to CM from control hepatocytes or HSC without CM exposure, respectively. Summary and Conclusion: These data indicate that lipid accumulation in hepatocytes causes the secretion of soluble mediators that induce activation of HSC as well as proliferation and expression of pro-fibrotic and pro-inflammatory genes in activated HSC. These findings demonstrate a potential mechanism how hepatic lipid accumulation contributes to the progression of inflammation and hepatic fibrosis in NAFLD. This study therefore provides an attractive in vitro model to study molecular mechanisms of fibrogenesis in NASH and to establish potential anti-inflammatory and anti-fibrotic therapeutic strategies.

1185 DIETARY CONSTITUENTS IN MICE ARE REFLECTED IN THE HEPATIC LIPID PROFILE AS DETECTED BY CARBON-13 MAGIC ANGLE SPINNING MAGNETIC RESONANCE SPECTROSCOPY

Jeremy F. Cobbold1, Suchitra Chinthapalli2, Quentin Anstee1, Robert D. Goldin2, Roger Cox3, Mark R. Thursz1, Howard C. Thomas1, Simon D. Taylor-Robinson1, I. J. Cox4; 1Medicine, Imperial College London, London, United Kingdom; 2Investigative Sciences, Imperial College London, London, United Kingdom; 3Mammalian Genetics, Medical Research Council Harwell, Harwell, United Kingdom; 4Imaging Sciences, Imperial College London, London, United Kingdom

BACKGROUND AND AIMS: Techniques to enable assessment of hepatic lipids in intact tissue are required to assess the effect of dietary constituents on the development and progression of non-alcoholic fatty liver disease (NAFLD). Magic angle spinning magnetic resonance spectroscopy (MAS-MRS) is a quantitative, non-destructive technique for metabolic profiling of intact tissue. Studies have demonstrated that proton (1H) MAS-MRS can be used to detect and quantify lipid. In this proof-of-principle study, carbon-13 (13C) MAS-MRS was applied to the study of hepatic tissue from murine models of NAFLD. We aimed to validate 13C MAS-MRS by comparison with 1H MAS-MRS findings. We hypothesised that differences in the hepatic lipid profile, in response to feeding diets with differing quantities of total lipid, monounsaturated (MUFA) and polyunsaturated (PUFA) fatty acids, are detectable by 13C MAS-MRS. METHODS: 6 mice of the C3H/HeH strain (susceptible to steatohepatitis) were housed under standard conditions and were fed either standard diet (StD) (4.2% fat by mass; 33% monounsaturated, 46% polyunsaturated) or high fat (HFD) (24% fat; 45% monounsaturated, 18.5% polyunsaturated) diets from age 6 weeks to culling at 36 weeks. In vitro hepatic MAS-MRS was carried out using a 500MHz JEOL ECP NMR spectrometer, with spin speed of 3500Hz at 4°C. 13C, 1H and 2-dimensional (2D) heteronuclear multiple quantum correlation (HMQC) MR spectra were obtained. Spectral peaks were assigned using published data and cross-correlated using HMQC. Quantification was by integration of peaks divided by total signal. A MUFA to PUFA index (MUFA:PUFA) was derived from a ratio of lipid resonance integrals at 128 and 129.8ppm. Livers were graded histologically for steatosis, fibrosis and inflammation. RESULTS: High quality 13C MAS-MRS spectra were obtained from all samples. The total lipid was greater in HFD mice compared to StD (p<0.05) and lipid differences were consistent between 13C and 1H MR spectra (absolute lipid CH2 resonance 2.9x (13C) and 2.7x (1H) higher in HFD vs StD). The mean (±SEM) MUFA:PUFA index was 1.7 (±0.15) in the HFD group versus 0.35 (±0.09) in StD (p=0.001), closely reflecting dietary constituents. A higher MUFA:PUFA index was also associated with increased disease severity as assessed histologically. CONCLUSIONS: 13C MAS-MRS has been applied to the study of intrahepatic lipid in intact tissue in response to dietary intervention and demonstrates a quantitative lipid profile, which corresponds to both dietary constituents and disease severity. This technique may be applied to further murine models and diets, and the findings translated to longitudinal in vivo studies.
1186 ADENOVIRUS-MEDIATED TRANSFER AND INDUCTION OF HEPATIC HEME OXYGENASE-1 IN THE LIVER PROTECTS AGAINST STEATOHEPATITIS IN VITRO AND IN VIVO

Jun Yu, Eagle SH Chu, Ruizhi Wang, Chung W Wu, Yim P Wong, Enders KW Ng, Henry LY Chan, Joseph JY Sung; The Chinese University of Hong Kong, Hong Kong, China

Background and Aims: Non-alcoholic fatty liver disease can range from a benign condition (steatosis) to inflammation, and fibrosis (steatohepatitis). Oxidative stress has been suggested to play a novel role in transition from steatosis to steatohepatitis. Heme oxygenase-1 (HO-1), an antioxidant defense enzyme, has been shown to protect against oxidant-induced tissue injury. The aim of the present study was to investigate the role of HO-1 induction by adenovirus-mediated gene transfer or by chemical inducer in nutritional steatohepatitis both in vitro and in vivo. Methods: AML-12 hepatocytes were cultured in lipogenic medium and transfected with or without a recombinant adenovirus expressing the HO-1 gene (Ad-HO-1) or with or without HO-1 inducer SnMP (0, 1, 3, 5, 10 and 15 µM) or HO-1 inhibitor SnMP (0, 1, 3, 5, 10 and 15 µM) for up to 24 hours. Male C57BL6 mice were fed MCD or the control diet, with or without HO-1 inducer Hemin (25 mg/kg, 3 times per week) or HO-1 inhibitor SnMP (30 µM/kg, once weekly) for up to 3 weeks. AML-12 cells or livers were assessed for inflammatory and hepatocellular injury, triglyceride content, lipid peroxidation and HO-1 levels. Results: AML-12 cells exposed to MCD medium developed significant steatosis, increased loss of ALT into the medium and increased oxidative injury. Infection of AML-12 cells with Ad-HO-1 resulted in a dose-dependent increase in the expression of HO-1 mRNA and protein concomitant with a dose-dependent suppression of steatosis (0.16±0.03 mmol/L at highest Ad-HO-1 concentration vs 0.25±0.01 MCD control), ALT (71.0±8.0 U/L vs 207.5±7.8) and lipid peroxidation levels (1.96±1.03 nmol/mg protein vs 4.76±0.83). A similar effect was observed by treated with Hemin. Co-treatment with SnMP completely abolished Ad-HO-1 or Hemin-mediated protection in hepatocytes. Treatment of mice with hemin significantly attenuated MCD-induced steatohepatitis. In contrast, the severity of liver histology was more pronounced in MCD feeding mice treated with SnMP compared with MCD only. Conclusions: Our results have demonstrated that HO-1 is critical in the progression of nutritional steatohepatitis. Induction of HO-1 through adenovirus-mediated transfer of the HO-1 gene or HO-1 inducer may provide a novel therapeutic approach in treating this disorder.

1188 GREEN TEA POLYPHENOLS IMPROVE LIVER INJURY OF NONALCOHOLIC STEATOHEPATITIS (NASH) MODEL MICE EXPRESSING NUCLEAR STEROL REGULATORY ELEMENT-BINDING PROTEIN 1C (nSREBP-1c) IN ADIPOSE TISSUE

Takato Ueno1,2, Toru Nakamura2,1, Ryuichiro Sakata2,1, Osamu Hashimoto2,3, Kinya Inoue2,1, Hirohori Koga2,1, Takuii Torimura2,1, Masako Shinikawa1, Hitomi Nakayama2, Syuichi Otabe3, Naotoshi Hirota2, Kentaro Yamada3, Michio Sata2,1; 1Research Center for Innovative Cancer Therapy and Center of the 21st Century COE Program for Medical Science, Kurume University, Kurume, Japan; 2Division of Gastroenterology, Department of Medicine, Kurume University School of Medicine, Kurume, Japan; 3Division of Endocrinology and Metabolism, Department of Medicine, Kurume University School of Medicine, Kurume, Japan

Background/Aim: Part of patients with NASH progress to end-stage liver disease such as cirrhosis and hepatocellular carcinoma, and the therapy of NASH is very important. In the present study, we examined whether green tea polyphenols (GTPs) including catechins improve liver injury of NASH model mice expressing nuclear sterol regulatory element-binding protein 1c (nSREBP-1c) in adipose tissue. Materials and Methods: nSREBP-1c transgenic C57BL6 male mice aged 30 weeks, that showed the typical NASH in liver histology at this age, were prepared in this study. These mice were shared three groups (Group 1; mice given water containing high dose GTPs (0.1%), Group 2; mice given water containing low dose GTPs (0.01%), and Group 3; control mice given water without GTPs). After treatment for 12 weeks, these mice were bled, humanely killed and examined as follows. 1) Ratio of liver weight to body weight, 2) Biochemical assays containing serum AST and ALT. 3) Morphometry of liver specimens according to the grading and staging of NASH proposed by Brunt et al., 4) Immunohistochemistry using antibody of 8-hydro-2'-deoxygenansine (8OhdG) to estimate oxidative stress, 5) Western blotting using antibodies of insulin receptor (IR), insulin receptor substrate (IRS)-1 and phosphorylated IRS-1 (pIRS-1) for insulin signaling, and using antibodies of Akt, pAkt, pIKKβ, NFkβ and pNFkβ for TNFα signaling. Results: 1) Ratio of liver weight to body weight in the high dose GTPs-treated group (group 1) was significantly lower than those of the groups 2 and 3 (p<0.05, respectively). 2) Blood AST, ALT, glucose, total cholesterol, and triglyceride levels of the group 1 were significantly low compared with that of the GTPs-no treated group (group 3) (p<0.05, respectively). 3) The degrees of steatosis, inflammation, ballooning hepatocytes, Mallory bodies, lipogranuloma and fibrosis in the group 1 significantly improved compared with those in the group 3 (p<0.01, respectively). 4) 8OhdG immunolocalization in liver tissues of the group 1 obviously decreased compared with those of the groups 2 and 3. 5) In Western blotting, the expressions of IR and pIRS-1 in liver tissues of the group 1 increased compared with those of the groups 2 and 3. On the other hands, the expressions of pAkt, pIKKβ and pNFkβ decreased compared with those of the groups 2 and 3. Conclusions: These results indicate that GTPs have the effects of anti-inflammation, anti-insulin resistance and anti-oxidative stress, and improve the liver injury of the transgenic mice expressing nSREBP-1c in the adipose tissue. Moreover, GTPs containing catechins are suggested to be useful for the therapy of patients with NASH

The following people have nothing to disclose: Takato Ueno, Toru Nakamura, Ryuichiro Sakata, Osamu Hashimoto, Kinya Inoue, Hirohori Koga, Takuii Torimura, Masako Shinikawa, Hitomi Nakayama, Syuichi Otabe, Naotoshi Hirota, Kentaro Yamada, Michio Sata

1189 TRANS-FATTY ACID POTENTIATES ACCUMULATION OF TRIGLYCERIDE AND SUSCEPTIBILITY TO OXIDATIVE STRESS IN HEPATOCYTES

Kazuyoshi Kon, Kenichi Ikejima, Tonomori Aoyama, Kyoko Okumura, Kumiko Arai, Sumio Watanabe; Gastroenterology, Juntendo University, Tokyo, Japan

Intake of trans-fatty acid is well known as potent risk factor of coronary heart disease. It has been reported that trans-fatty acid can aggravate insulin resistance, however, it has not been addressed the effect of trans-fatty acid on steatohepatitis. Therefore, our aim in this study was to investigate the effect of trans-fatty acid on fatty accumulation and susceptibility to reactive oxygen species (ROS) in isolated mouse hepatocytes. Methods: Hepatocytes were isolated from C57BL/6 mice 12 weeks after birth by collagenase perfusion and differential centrifugations, and cells were incubated in Waymouth's medium supplemented with 10% FBS for 20 hours. Cells were preincubated for 20 hours with oleic acid (cis-fatty acid, 0.1-1 mM) or elaicid acid (trans-fatty acid, 0.1-1 mM), and accumulation of triglyceride in hepatocytes was identified by Oil red O staining. Cell killing and production of ROS in isolated hepatocytes were determined fluorometrically using propidium iodide and 5-(and-6)-chloromethyl-2',7'-dichlorodihydrofluorescein diacetate acetyl ester (DCF), respectively. Results: Hepatocytes treated with 1 mM oleic acid accumulated triglyceride deposit in cytosol occupying 8±1% of cell area, and treatment with elaicid acid increased accumulation of triglyceride deposit to 20±2%, significantly (p<0.001). Exposure to 20 µM tert-butyl hydroperoxide (t-BuOOH), which induces NAD(P)H oxidation and mitochondrial ROS generation, did not cause significant cell killing within 30 min, and when cells were pretreated with 1 mM oleic acid, t-BuOOH did not affect until 20 min and increased cell killing to 29±3% after 30 min (p<0.05). Surprisingly, treatment with 1 mM elaicid acid increased cell killing even after 15 min of treatment significantly (p<0.05 vs. control) and reached to 34±3% after 30 min. Exposure to 20 mM t-BuOOH increased DCF fluorescence to 354±25% of baseline. Increment of DCF fluorescence after t-BuOOH was enhanced by pretreatment with 1 mM oleic acid to 488±34% of baseline after 30 min, and 1 mM elaicid acid increased DCF fluorescence to 59±21% of baseline after 30 min, significantly (p<0.05, vs. oleic acid). Pretreatment with elaicid acid at concentration as low as 0.1 mM increased DCF fluorescence after t-BuOOH to 489±42% of baseline significantly (p<0.05, vs. control), whereas 0.1 mM oleic acid did not affect DCF fluorescence. Conclusions: Our data demonstrated that trans-fatty acid enhances fatty accumulation and increases susceptibility to t-BuOOH-induced mitochondrial ROS generation in isolated hepatocytes. Therefore, it is concluded that trans-fatty acid is a potent exacerbating factor for hepatocellular injury in steatohepatitis.

1190 LOSS OF β-CATENIN EXACERBATES MEHONINE-CHOLINE-DEFICIENT DIET INDUCED STEATOHEPATITIS IN MICE

Jaideep Behari1, Wade Otruba1, Benjamin Cieply2, Udayan Apte2, Tong Wu2, Sadasrhan P. Manga1,2; 1Department of Medicine, University of Pittsburgh, Pittsburgh, PA; 2Department of Pathology, University of Pittsburgh, Pittsburgh, PA

Background and Purpose: The protein β-catenin plays an important role in liver development, growth, and homeostasis. The
purpose of this study was to evaluate the effect of the methionine-choline-deficient (MCD) diet, which induces steatohepatitis in wild-type mice, in liver-specific β-catenin knockout mice. Methods: Mice with liver-specific disruption in β-catenin and wild-type littermates were fed MCD or control (replete in methionine and choline) diets for 2 weeks. Animals were then sacrificed for analysis of liver histology, gene expression by real-time PCR, and serum biochemistries. Results: On the MCD diet, β-catenin knockout animals exhibited striking macrovesicular hepatic steatosis (80-100%), grade 3-4 inflammation, and stage 1-2 fibrosis, compared with mild to moderate steatosis and no fibrosis in control animals. On the control diet, knockout mice had mild microvesicular steatoh hepatitis and two-fold higher serum transaminases compared with normal histology and transaminase levels in wild-type animals. Knockout mice had higher levels of hepatic lipid peroxidation on both control and MCD diets. No significant change in total β-catenin protein levels was noted in wild-type animals on the MCD diet. In knockout mice, liver injury occurred despite low expression of peroxisomal Cytochrome P450 2E1, a downstream target of β-catenin. Knockout mice had significantly lower expression of Peroxisome proliferator-activated receptor-alpha and microsomal triglyceride transfer protein, suggesting that decreased beta-oxidation of fatty acids and defective very low density lipoprotein secretion may be responsible for the liver phenotype seen in the knockout mice. Expression of SREBP1 was decreased in the knockout mice on the MCD diet, which may represent a compensatory decrease in lipid biosynthesis. Conclusion: Liver-specific β-catenin knockout mice show striking increase in liver injury on the MCD diet, suggesting an important protective role of β-catenin in the pathogenesis of liver injury in this model of steatohepatitis.

Dietary zinc supplementation reverses alcoholic fatty liver in the presence of chronic alcoholic administration
Zhanxiang Zou, Xinqin Kang, Zhenyuan Song, Craig J. McClain, Y. James Kang; University of Louisville, Louisville, KY

Zinc deficiency has been documented in alcoholic liver disease and may contribute to the pathogenesis of liver injury. Alcoholic fatty liver, which is characterized by lipid droplets in the hepatocyte, is one of the earliest pathologic changes in the liver. The present study was undertaken to determine whether or not dietary zinc supplementation modulates lipid metabolism through regulation of gene expression, thereby attenuating alcoholic fatty liver. Mice (129 SEV) were pair-fed Lieber-DeCarli liquid diets containing alcohol or isocaloric maltose dextrin for 3 months, followed by dietary zinc supplementation for 3 weeks with the concomitant presence of alcohol exposure. Chronic alcohol exposure caused hepatic steatosis as demonstrated by oil red O staining and quantitative assay of triglyceride and cholesterol concentrations. Zinc supplementation reduced alcohol-induced lipid accumulation in the liver. To understand the mechanism of zinc action, the gene expression involved in lipogenesis, fatty acid β-oxidation, and very-low-density lipoprotein (VLDL) secretion were determined by real time RT-PCR assay. Zinc supplementation significantly increased the mRNA levels of acyl-coenzyme A dehydrogenase, microsomal triglyceride transfer protein, and apolipoprotein B, although the fatty acid synthase was not affected by zinc. Zinc supplementation also enhanced the gene expression of transcription factors involved in regulation of lipid metabolism, including hepatocyte nuclear factor-4α, PPAR-α and C/EBP. The capacity of lipid export from the liver was estimated by in vivo assay of VLDL triglyceride secretion using the Triton WR1339 method. The secretion rate of hepatic VLDL triglycerides was decreased by alcoholic exposure, but increased by zinc supplementation. These results suggest that zinc reverses alcoholic fatty liver, at least in part, by enhancing both fatty acid β-oxidation and the lipid export capacity. (Supported in part by the National Institutes of Health grants and the Veterans Administration, Louisville)

Caveolin-1 upregulates endothelial capillary-like tubular formation and fenestral contraction in association with Rho GTPases in sinusoidal endothelial cells
Hiroaki Yokomori1, Masaya Oda2, Toshifumi Hibi3; 1Internal Medicine, Kitasato Medical Center Hospital, Saitama, Japan; 2Organized Center of Clinical Medicine, International University of Health and Welfare, Tokyo, Japan; 3Internal Medicine, School of Medicine, Keio University, Tokyo, Japan

Background and aims: Endothelial tubular formation depends on cell migration, adhesion, and proliferation. Rho GTPases are major regulators of cell polarization and motility. Caveolin-1 (Cav-1) is essential for caveolae formation. We have proposed that hepatic sinusoidal endothelial fenestrae (SEF) correspond to the fused and interconnected caveolae. The present study was designed to elucidate the roles of the cytoskeleton, Rho GTPases, and Cav-1 processes in isolated rat sinusoidal endothelial cell (SEC) s in vitro tube formation. Materials and Methods: The SECs obtained from rat livers by collagenase infusion method were subjected to primary monolayer culture on Matrigel for 5-18 hours. The morphology of was observed by scanning electron microscopy (SEM), transmission electron microscopy (TEM). Formation of F-actin stress fibers was observed by confocal microscopy. RhoA, Rac1 and phosphorylated myosin light chain kinase were analyzed by Western blotting. Rho and Rac activation were measured by the binding assays. Results: The overlay of Matrigel initially induced changes in endothelial cell morphology characterized by the formation of dynamic cellular protrusions, enhancing cell migration and finally leading the assembly of discrete aggregates or cords of aligned cells resembling primitive capillary-like structures, concomitant with a decrease in number and diameter of the characteristic SEF. In this process, time course analysis of RhoA and Rac1 activation matches specific morphological aspects. Rho A activation increased at 5 hr, and then declined after 6 hr, but increased again at 18 hr. The second increase of RhoA activation corresponded to the stage of stress fibers formation running along the major cell axis. During the remodeling phase of network formation, the SECs showed an intense staining for phosphorylated MLC by Western blotting. Rac1 activation was detected at 5 hr, then progressively decreased and lower than the basal level after 18 hr. The levels of endogenous Cav-1 expression increased in a time-dependent manner when endothelial cells underwent proliferation, reaching the maximum level of 6 hr. Cav-1 expression occurred just prior to the formation of capillary-like tube. Conclusions: Spatial activation of Rac1 and RhoA is considered to be involved in the formation of capillary-like tubular network accompanying fenestral contraction in SEC, implying that endothelial migration and...
adhesion are essential for sinusoidal angiogenesis in the liver. Taken together, the above results indicate that Cav-1 may play an important role in the regulation of SEC proliferation as a prerequisite step in the process of angiogenesis.

ROLE OF THE N-TERMINAL SEQUENCE OF BSEP (ABCB11) IN PROTEIN TRAFFICKING AND STABILITY

Claire L. Pearson, Ping Lam, James L. Boyer; Internal Med., Yale University, New Haven, CT

Background: The bile salt export pump (Bsep, Spgp, ABCB11) is a polytopic membrane glycoprotein that exports bile salts out of the hepatocyte across the apical (canalicular) membrane into the bile canaliculus. The molecular mechanisms responsible for targeting Bsep to the apical membrane and its dynamic trafficking are poorly understood. It is suggested that Bsep has a unique trafficking pattern as it leaves the Golgi and goes to an intermediate compartment before it reaches the apical membrane. Comparison of the different Bsep and MDR1 homologues indicate that the N-terminus of Bsep is highly divergent.

Aim: To understand the role of the divergent N-terminus in Bsep trafficking and protein stability. Methods: We have generated a series of N-terminus deletion mutants of rat Bsep by primer design deletion including, Δ19, Δ38, Δ56, Δ61 and one C-terminal deletion of Δ5 amino acids, fused to yellow fluorescent protein (YFP) at the C-terminus. Constructs were transiently transfected into both a non-polarized human derived kidney cell line (HEK293) and the polarized canine derived kidney cell line (MDCK) in order to investigate cellular localization by confocal microscopy. In addition, cell lines that stably express the different mutant proteins were isolated for biochemical analysis. Western blots were used to measure the mutant protein levels, the effects of temperature shift on protein expression, and half-life. Results: In both polarized and non-polarized cells lines Bsep-YFP localizes to the apical and plasma membrane. Nevertheless expression levels are lower in the cells expressing deletions of Bsep compared to the wild type construct, indicating that the mutant protein might be unstable and partially degraded as they traffic to the apical membrane. Removal of up to 38 amino acids from the N-terminus has no effect on Bsep localization to the apical membrane. Both the wild type Bsep and the Δ38 have complex glycosylation indicated by PNGase F and EndoH treatment. Removal of 56 amino acids or more from the N-terminus causes Bsep to localize to intracellular compartments. Immunofluorescence of the Δ56 suggests that the protein localizes in the ER. Conclusion: The results of this study suggest that the N-terminus amino acid sequence of Bsep does not have an apical localization sequence. The deletion of the first 38 amino acids of Bsep still reaches the apical membrane. The larger deletion up 56 amino acids inhibits apical localization of the mutant protein in the ER, possibly due to changes in protein folding or stability. Thus it suggests that the N-terminus of Bsep is important for protein folding or stability.

LIVER CELL VOLUME REGULATION AND ATP RELEASE REQUIRE INTACT VESICULAR TRAFFICKING PATHWAYS

Meghana N. Sathe1, Andrew P. Feranchak1, J. Gregory Fitz2, Charles Kresge1; 1Pediatrics, UTSW, Dallas, TX; 2Internal Medicine, UTSW, Dallas, TX

Physiological changes in liver cell volume serve as a signaling pathway that modulates a broad range of liver functions. Following solute uptake, hepatocyte volume increases, this in turn initiates an adaptive regulatory volume decrease (RVD). RVD depends on cellular ATP release and autocrine stimulation of P2 receptors. In neuronal cells, ATP release depends on exocytosis of ATP-enriched vesicles. The role of vesicular trafficking pathways in liver cell ATP release and RVD are unknown. The aim of the present study was to determine the role of vesicular trafficking in ATP release and RVD in a hepatocyte model. METHODS: Studies were performed in HTC rat hepatoma cells. Changes in cell volume were measured by Coulter Multisizer and ATP release by a luciferin-luciferase assay, reported as arbitrary light units (ALU). RESULTS: Exposure to hypotonic buffer (20%) resulted in relative increase in cell volume of 1.25 +/- 0.06 followed by complete RVD (100% recovery to basal levels) by 15 minutes. Incubation of cells with monensin, which disrupts secretory vesicle formation, inhibited RVD to only 43%, while exposure to nocodazole, which disrupts microtubules, resulted in RVD of only 41%. In parallel studies, hypotonic exposure (25%) increased relative ATP release by 3.96 +/- 0.43 ALU. Volume-stimulated ATP release was attenuated by both monensin (2.57 +/- 0.15 ALU, p<0.01) and nocodazole (1.79 +/- 0.08 ALU, p<0.01). Since neuronal synaptic vesicle exocytosis requires “priming” by PKC, the effects of a panel of PKC isoform-selective agents were assessed on volume-stimulated ATP release in HTC cells. Chelerythrine, which inhibits all PKC isoforms, decreased volume-stimulated ATP release by 56.1 +/- 6.4 % and calphostin C, which inhibits conventional and novel isoforms, decreased ATP release by 56.8 +/- 11.3% (p<0.01). Acute exposure to phorbol 12-myristate 13-acetate (PMA), which activates conventional and novel PKC isoforms, did not affect basal ATP release, but significantly augmented relative ATP release by 6.43 +/- 1.2 ALU after hypotonic exposure (25%) vs. 2.7 +/- 0.1 ALU without prior PMA (p<0.05). CONCLUSION: Together these studies demonstrate that i) liver cell volume regulation and ATP release require intact vesicular trafficking pathways, ii) PKC is necessary but not sufficient for ATP release, and iii) volume-stimulated ATP release is potentiated by PKC activation. These findings suggest that PKC may be functioning in part to dock or prime a pool of ATP-containing vesicles so that they enter a readily-releasable state responsive to other signals.

THE SORTING OF ENDOCYTIC PROTEIN ALONG ACTIN AND MICROTUBULES IN THE HEPATOCYTE

Souvik Sarkar, Allan W. Wolkoff, John W. Murray; Liver Research Center, Albert Einstein College of Medicine, Bronx, NY

Introduction: Viruses, proteins, lipids and other molecules enter cells through endocytosis wherein they enter a complex of intracellular vesicles and tubules that undergo movement, fusion, and fusion along the cytoskeleton, as demonstrated here using primary rat hepatocytes. Presumably, these cytoskeletal-based processes lead to the sorting of endocytic material to different cellular compartments. However, previous studies using
Depolymerizing drugs have shown that vesicle processing leading to protein segregation can occur in the absence of an intact cytoskeleton. **Methods:** To determine if microtubule and actin-based movement of endosomes can lead to the segregation of protein, individual endocytic vesicles and their cargo were tracked during high resolution, multi-channel fluorescence microscopy assays using endocytic vesicles that were purified from rat liver as well as primary cultured rat hepatocytes. **Results:** An in vitro biochemical assay successfully reconstituted both actin and microtubule based movement associated with endocytic processing. Endocytic cargo underwent fission and protein segregation along actin and microtubules at characteristic rates. Fission resulted in the segregation of proteins that are targeted for different cellular compartments. The bile salt transporter (ntcp) and transferrin receptor (TR), segregated away from asialoorosomucoid (ASOR), an endocytic ligand targeted for degradation, while the epidermal growth factor receptor (EGFR), which is degraded, and the asialoglycoprotein receptor (ASGPR), which remains partially bound to ASOR, segregated less efficiently from ASOR. Fission rates for ntcp and transferrin receptor were dramatically elevated when in the presence of the ASOR ligand. Additionally the inhibition of PI3-Kinase reduced fission but not overall motility indicating that PI3-Kinase functions in the fission of intracellular vesicles. **Conclusion:** The segregation of protein was achieved by the generation of ‘pure’ vesicles, which were depleted of endocytic ligand. Pure vesicles resulted from cytoskeletal based trafficking both in living hepatocytes and in the reconstituted in vitro assay. The identification and modulation of the cytoskeletal based fission machinery has implications for diverse fields such as drug delivery and viral replication.

**PROTEOMIC AND IMMUNOFLOURESCENCE ANALYSIS OF EARLY AND LATE ENDOCYTIC VESICLES ISOLATED FROM RAT HEPATOCYTES**

Subhajit Mukherjee1,2, Jean J. Wang2, Fa-Yun Che3, Kristie Gordon4, Linda Siconolfi-Baez4, Edward Nieves4, Ruth H. Angeletti3, John W. Murray1,2, Allan W. Wolkoff1,2, 1Anatomy and Structural Biology, Albert Einstein College of Medicine, Bronx, NY; 2Marion Bessin Liver Research Center and Division of Hepatology, Albert Einstein College of Medicine, Bronx, NY; 3Developmental and Molecular Biology, Albert Einstein College of Medicine, Bronx, NY; 4Biochemistry, Albert Einstein College of Medicine, Bronx, NY; 5Herbert Irving Comprehensive Cancer Center, Columbia University, New York, NY

**Introduction:** In hepatocytes, following binding of asialoorosomucoid (ASOR) to the asialoglycoprotein receptor (ASGPR), the complex internalizes into early endocytic vesicles that acidify, resulting in dissociation and eventual segregation of the receptor-ligand complex into discrete vesicles. The proteins that mediate these events have been only partially elucidated. To identify and characterize the molecular mediators of this endocytic processing we have developed a proteomic and immunofluorescence based analysis of purified early and late endocytic vesicles. **Methods:** Early and late endocytic vesicles were isolated from rat livers that were removed at 5 and 15 minutes respectively after portal venous injection of fluorescent ASOR. Following partial purification by gel chromatography and sucrose gradient centrifugation, fluorescent vesicles were highly purified by flow cytometry. Sorted endocytic vesicles were subjected to 1D SDS-PAGE and gel slices were digested with trypsin and peptides were analyzed by nanoLCMS/MS. Using Mascot search criteria with peptide score of ≥45 and with peptide hits ≥ 2 or more, over 200 proteins were identified. **Results:** Aside from the ASGPR, a number of integral membrane proteins were identified, including the bile salt export pump, and organic anion and glucose transporters. Several Rab and SNARE proteins were identified, as well as motor proteins including dynein heavy chain, myosin 1 heavy chain and non-muscle myosin heavy chain A. To validate identification of proteins in vesicles, we employed an in vitro microscopy assay to quantify co-localization between the identified proteins and vesicles containing fluorescent ASOR. 92% (n=1145) of 5 min ASOR-containing early vesicles and only 19% (n=453) of the 15 min ASOR-containing late vesicles co-localized with the ASGPR, consistent with late vesicles being largely post segregation. Rab 1a (early-52%, late-36%), Rab 8a (early-67%, late-54%), Rab 14 (early-76%, late-78%), and Rab 18 (early-58%, late-54%) were highly co-localized with both early and late vesicles. Rab27a (early-22%, late-58%) and SNAP-23 (early-35%, late-64%) were more enriched in late as compared to early vesicles. **Conclusions:** Proteins that may be important in vesicle trafficking and processing (e.g. Rab’s and SNAP’s) have been discovered by proteomic analysis of endocytic vesicles that have been highly enriched by flow cytometry. We hypothesize that these proteins, which were previously not known to be associated with these endocytic vesicles, form a scaffold that directs interaction of these vesicles with other regulatory and motor proteins. This will be examined in future studies.

1198 EMODIN IMPAIRS THE REARRANGEMENT OF ADHESION MOLECULES INDUCED BY HCV

Anna Alisi, Alessandra Spaziani, Simona Anticoli, Clara Balsano
University of L'Aquila, L'Aquila, Italy

Hepatocellular carcinoma (HCC) is a common malignancy in the world. Unresectable or metastatic HCC carries a poor prognosis, and local, nonsurgical therapies are applied. In our study of the role of hepatitis C virus (HCV) proteins in inducing progression of HCC, leading cells to spread in liver tissue and promoting metastasis, we investigated the role of HCV proteins in regulating the invasive properties of human HCC cell line, HepG2. HepG2 cells were used to establish stable polyclones expressing the entire genome or core protein of HCV. When we examined cells for their differences in invasion ability we found that HCV proteins influence HCC cell adhesion and cell migration. Since adhesive and migratory ability of cells depends on expression, localization and activity of a cluster of proteins named focal adhesion molecules, we performed a deeply analysis by using western blotting, fluorescence and immunoprecipitation techniques. Our results demonstrate that in HCV positive polyclones, FAK (focal adhesion kinase) as well as beta1-integrin and paxillin are over-expressed. In addition, HCV proteins alter localization of beta1-integrin and alpha-actinin and induce activation of FAK. The silencing of HCV core protein by a specific small interference RNA (siRNA) completely abrogates HCV-related effects. To assay a possible gene therapy approach we used a specific siRNA against FAK. FAK silencing only partially reverted the HCV-dependent focal adhesion dysregulation, thus we treated cells with emodin, an anthraquinone derivative, with anti-microbial, immunosuppressive and anti-proliferative effects. Interestingly, emodin was able to completely abrogate the acquired HCV-related invasiveness of cells, fact probably due to its capacity to influence both ECM molecules and a wide range of intracellular pathways, which include FAK but also other kinases such as PI3K/AKT, MAPK, and PKC.

1199 EFFECTS OF HINT2, A PUTATIVE TUMOR SUPPRESSOR, ON MITOCHONDRIAL FUNCTIONS

Olivier Maurhofer, Dagmar Hahn, Monika Ledermann, Karin Schmitter, Juliette Martin, Jean-Francois Dufour
Department of Clinical Pharmacology, University of Berne, Berne, Switzerland; Department of Clinical Chemistry, Inselspital, Berne, Switzerland

Background: We identified HINT2, a protein expressed predominantly in the liver and the first human HIT protein to be localized in mitochondria. HINT2 is an AMP-lysinase hydrolase. We reported that over-expression of HINT2 sensitizes cells to Fas-induced apoptosis and that expression of HINT2 was down-regulated in hepatocellular carcinoma. Aim: to investigate the effects of HINT2 expression on mitochondria functions. Methods: HepG2 cells stably transfected to over-express HINT2 (20-fold excess), cells stably transfected to knock down HINT2 expression (10-fold decrease) and cells transfected with each control vectors. Enzymatic activities of the respiratory chain complexes were measured. Oxygen consumption of isolated mitochondria was assessed with a Clark-type electrode. Data were normalized to the activity of the citrate synthase. Oxygen consumption of whole cells was measured by high-resolution respirometry using an Oroboros Oxygraph-2k. Intracellular ATP levels were determined with kit HS II (Roche Applied).

Results: In isolated mitochondria, the activities of the complexes I to IV as well as the oxygen consumption were not affected by modifications of HINT2 expression. Respirometry on whole cells expressing less HINT2 show consistently less state 3 respiration in the presence of ADP using pyruvate/malate, succinate or ascorbate/TMPD as substrates respectively. This was associated with a significantly lower intracellular ATP content. Conclusion: Diminished expression of HINT2 impairs cellular respiration and affects ATP content. These effects are detected at the level of the whole cells and not at the level of isolated organelles suggesting on effect on the cellular mitochondrial mass.

1200 HEPATITIS C VIRUSINDUCES IFN-A IN PLASMACYTOID DENDRITIC CELLS AND AFFECTS DIFFERENTIALLY STIMULATION VIA TOLL-LIKE RECEPTORS 7 AND 9

Francoise Gondois-Rey, Philippe Halton, Clelia Dental, Daniel Olive, Ivan Hirsch, INSERM UMR599 Centre de Recherche en Cancérologie de Marseille, Marseille, France; Institut Paoli-Calmettes, Marseille, France; Université Méditerranée, Marseille, France; Laboratoire Alphabio, Marseille, France

Plasmacytoid dendritic cells (PDC) are responsible for production of a vast amount of type I IFN during viral infection. Therefore, eradication of hepatitis C virus (HCV) in more than 50% of chronically infected patients treated with IFN-a-based therapy suggests a major role of PDC in the control of HCV infection. In previous studies, the functional activity of PDC obtained from patients with chronic HCV infection was tested after ex vivo exposure to synthetic stimulators of Toll-like receptor 7 (TLR7) or TLR9. Here, we assayed the direct effects of HCV on functionality of purified PDC. We found that exposure of PDC to molecular clone HCV JFH-1 or to HCV from sera of chronically infected patients resulted in production of IFN-a and TNF-a.
an optimal multiplicity of infection, the HCV-exposed PDC produced significantly less IFN-α and TNF-α than did PDC exposed to influenza virus or human herpesvirus type 1. HCV did not induce maturation of PDC and had no effect on PDC apoptosis. Our experiments with thymoactivated virus and with inhibitors of endocytosis suggest that HCV stimulates PDC predominantly via TLR by the endocytosis pathway. Importantly, HCV reduced PDC-associated production of IFN-α induced with TLR9 agonist CpG more profoundly than that stimulated with TLR7 agonist resiquimod. Differential effect of HCV on stimulation of PDC via TLR7 or TLR9 may be important in the development of new anti-HCV therapies based on TLR agonists.

HEPATIC STEATOSIS AND GLOMERULAR DISEASE IN MICE WITH C-TERMINALLY TRUNCATED GP73 (GOLPH2)

Lorinda M. Wright1,2, Maria Picken3, Sherri Yong2, Don C. Rockey4, Scheherazade Nisar2, Claus J. Fimmel1,2; 1Division of Gastroenterology, Hepatology and Nutrition, Loyola University, Chicago, IL; 2Research (151), Hines VA Hospital, Hines, IL; 3Department of Pathology, Loyola University, Stritch School of Medicine, Chicago, IL; 4Internal Medicine, Digestive & Liver Diseases, UT Southwestern Medical Center, Dallas, TX

GP73 (Golph2) is a type II integral membrane Golgi-localized protein of unknown function that is expressed constitutively in epithelial cells of many human tissues. GP73 is overexpressed in hepatocytes of patients with liver disease, and appears in the serum of hepatocellular cancer patients (Marrero, J.A., et al., J Hepatol 43:1007; Block, T.M., et al., PNAS 102:779). We hypothesized that GP73 deficiency might affect epithelial tissue integrity. We tested this hypothesis using gene trap technology to generate mice with a truncation of the C-terminal 146 amino acids of GP73. The truncated protein is fused to a β-galactosidase (β-gal) marker. Expression analysis by RT-PCR and β-gal staining revealed that wild-type and truncated GP73 were highly expressed in epithelial cells of the murine gastrointestinal tract and uterus, but present at low levels in liver and kidney. Notably, carbon tetrachloride-induced liver injury was associated with increased mRNA levels of wild-type GP73. Homozygous GP73-truncated mice were born at the expected rate and were fertile; the life span of males was normal. In contrast, females exhibited a 50% reduced cumulative 1.5 year survival compared to wild-type controls. Increased mortality rates first became evident at age 3 weeks, and continued to rise to late adulthood. Death in homozygous females was due to severe renal disease, as evidenced by advanced glomerular sclerosis, glomerular enlargement, glomerular hyaline thrombi, and degenerative changes in the proximal tubules. Homozygous mice developed hepatic microvesicular steatosis, intranuclear inclusions, and striking circumferential nuclear membrane irregularities. These nuclear changes suggested a loss of hepatocyte nuclear membrane integrity, and possibly of membrane stability. The mechanisms responsible for kidney and liver abnormalities in GP73-truncated mice are under investigation. Our study suggests a role for GP73 in normal epithelial cell function in the liver and kidney. This model will be a valuable tool to help elucidate the role of GP73 in hepatic carcinogenesis and renal function.

PRIMARY HUMAN HEPATOCYTES UNDERGO DNA SYNTHESIS IN RESPONSE TO ENGINEERED FORMS OF HEPATOCYTE GROWTH FACTOR (HGF/SF): A PRE-REQUISITE TO USING HGF ANALOGUES CLINICALLY

Clare Selden1, Myrdiddin Rees2, Jennifer Mann1, Humphrey J. Hodgson1, Ermanno Gherardi2; 1Centre for Hepatology at the Royal Free, Royal Free & University College Medical School, London, United Kingdom; 2Medical School, University of Cambridge, Cambridge, United Kingdom; 3Dept of Surgery, North Hamshire Hospital, Basingstoke, United Kingdom

Hepatocyte Growth Factor (HGF/sf) is a 6-domain complex protein synthesised by mesenchymal cells, acting on target epithelial cells via a tyrosine kinase receptor (c-met). HGF/sf inactive single-chain precursor is converted to active two-chain form by cleavage of the linker connecting kringle 4 and sp domains. In experimental animals, HGF/sf can enhance regeneration, prevent and reverse fibrosis in chronic liver disease and enhance size and function at liver surgery. These effects would offer major therapeutic advantages if applicable in man, but production of wild-type protein is costly and difficult. Engineered variants of HGF/sf may offer advantages in respect of stability, altered ligand affinity, and ease of production, but require to be tested in human cells to justify development as therapeutic agents. Aim: To test the activity of engineered proteins in vitro in human hepatocytes by demonstrating the mitogenic effects of HGF/sf variants in human hepatocytes in culture, and the extent of DNA synthesis induced compared with wild type HGF/sf. Methods: We used the methylotrophic yeast P pastoris system to express hgf/sf fragments (Holmes 2007) nk1 and 1k1, using induction in BMGY medium and purification on Heparin-Sepharose CL-4B followed by cation exchange (Mono S) chromatography. We use the mouse myeloma N50 line for expression of full length proteins. Purification of hp21 mutant employed a Ni-NTA step prior to ion exchange. We dissociated the binding sites for the met receptor and for heparan-sulphate proteoglycans (HSPG) both in HGF/sf and in nk1. In nk1, which needs an intact high-affinity site, we mutated a secondary binding site for HSPG located in kringle 1, to create 1k1. Primary human hepatocytes were stimulated with nM doses of wild-type HGF/sf, HGF/sf21, nk1 or 1k1. 3Hthymidine incorporation was analysed in cells harvested for DNA. Results are expressed as fold stimulation over basal conditions. Results: Primary human hepatocytes undergo significant DNA synthesis in response to both wild-type (15-fold) and mutant (22-fold) HGF/sfs. The polypeptides (Nk1 and 1k1) although less active than wild type HGF/sf show a 3-4-fold stimulation. Conclusions: Engineered HGF isoforms, therefore, have the potential for use in man. The full length mutant hp21 is likely more active than the natural proteins in vivo as HSPGs greatly limit diffusion of the natural proteins in the tissue, and therefore access to target cells; moreover HSPG binding promotes degradation of HGF/sf. Whilst less active on a nanomolar basis than the full length protein, the polypeptides may have greater in vivo potential due to greater diffusivity and altered degradation.

1203 THE ROLES OF LYSOSOMAL PROTEINASES IN PRIMARY HEPATOCYTE DEATH INDUCED BY TNF-α AND ACTINOMYCIN D

Noriyuki Yamamura1, Toshiro Nishida1, Kiyokazu Nakajima1, Masahiro Shibata2, Masato Koike2, Yoshiki Sawa1, Yasuo Uchiyama2; 1Surgery, Osaka University Graduate School of Medicine, Suita, Japan; 2Cell Biology and Neurosciences, Osaka University Graduate School of Medicine, Suita, Japan

Tumor necrosis factor-α (TNF-α) is a cytokine signaling that is comprised in cell growth and apoptosis in the liver. It has been suggested that hepatocyte death in the liver induced by TNF-α is similar to the morbidity of liver dysfunction, while the mechanism of this hepatocyte death is caspase-dependent/apoptosis. Cathepsin B (CB), a lysosomal cysteine proteinase, has been shown to be involved in primary hepatocyte death induced by TNF-α and actinomycin D (TNF/ActD). Lysosomal proteinases including CB and cathepsin D (CD), an aspartic proteinase, have also been suggested to participate in the execution of the caspase-dependent or -independent cell death pathway, using various types of cells. In these cell death pathways, lysosomal proteinases are suggested to be released into the cytosol because of lysosomal destabilization, while released proteinases may further be involved in the caspase-dependent or -independent cell death pathway. However, the precise molecular mechanism of how lysosomal proteinases participate in caspase-dependent or -independent cell death remains controversial. We therefore examined how lysosomal proteinases participate in TNF/ActD-induced hepatocyte death (adult mouse liver, 25 ng/ml TNF-α and 0.2 µg/ml actinomycin D). The treated hepatocytes died within 12 hr, and lysosomal proteinases in TUNEL-positive hepatocytes were immunohistochemically localized in granules but not in the cytosol. Such hepatocyte death was prevented by the treatment with BAF or Z-VAD-fmk, a pan-caspase inhibitor, until 18 hr after the start of cultures. The survival rate of hepatocytes treated with BAF decreased to that of hepatocytes treated without BAF at 24 hr; dying hepatocytes frequently possessed TUNEL-positive nuclei without activated forms of caspase-3/-7 but with LC3-positive granules in the cytoplasm. Since CA074 is known to inhibit specifically CB at a lower dose (10 µM) and not only CB but also cathepsin L (CL) at a high dose (300 µM), we examined the survival rate of hepatocytes that were cultured in the presence of low and high doses of CA074, respectively; it was significantly higher at a higher dose than at a lower dose. Moreover, the survival rate of hepatocytes was further increased by the combined treatment of CA074 with a high dose and pepstatin A, and this survival rate was similar to that treated by BAF alone. Moreover, TNF-α-induced hepatocyte death was inhibited by the treatment with both BAF and CA074 + pepstatin A in an additive fashion. These results suggest that lysosomal proteinases such as CB, CL and CD is involved in the TNF/ActD-induced hepatocyte death pathway that is independent of the apoptotic pathway.

1204 NATURAL POLYMORPHISM OF NS3 PROTEASE DOMAIN STRAINS HCV-1 IN HCV AND HIV/HCV COINFECTED PATIENTS: VIROLOGICAL AND CLINICAL IMPLICATION FOR DRUG RESISTANT VIRUSES

Philippe Halfon1, Hawwa Dia1, Philippe Benech2, Patrick Philibert2, Agnès Martinet1, Guillaume Pénaranda1, Jérôme Courcambeck2, Mourad Bouzidi2, Hacène Khiri1; 1Laboratoire Alphabio, Marseille, France; 2Genoscience, Marseille, France; 3Hôpital Ambroise Paré, Marseille, France; 4CDL Pharma, Marseille, France

Background: HCV NS3 protease is a chymotrypsin-like serine protease responsible for cleavage of the non-structural proteins of HCV and plays a pivotal role in viral life cycle. Selection of drug-resistant mutants was evidenced by in vitro and clinical studies with HCV NS3-4A protease inhibitors (PIs). It appeared that the mutations A71T, T72I, P88L, R155Q, A156T, D168V were selected in each studies conferring resistance level to each PI. Aim: The aim of this study was to describe the natural polymorphism of NS3 sequence in different HCV 1 strains and to compare the diversity of the protease in HCV monoinfected patients and in HIV/HCV coinfected patients receiving an HIV Protease inhibitor. Methods: 24 mono-infected genotype1 patients (13 g1b and 11 g 1a) and 24 HCV/HIV coinfected patients receiving anti-HIV PI therapy were selected in this study. NS3 protease domain was amplified by RT-PCR. PCR products were purified and directly sequenced (54-197). Multiple alignment of nucleotide and deduced amino acid sequences was inferred by Clustal_X version 1.64b. Statistical analysis was performed using Fisher’s exact test to compare the proportion of mutation at position 71, 72, 155, 156 and 168; Wilcoxon rank-sum test to evaluate if patients mono-infected and HIV/HCV co-infected had different clinical and virological variables distributions. Results: The mutation rate observed in the different position were not different for HCV and HIV mono-infected patients. No difference in aa sequences were found between genotype 1a and genotype 1b patients. Diversity on the protease was more frequently observed in position : 71, 72 whereas the position 155, 156 and 168 were well conserved whatever the subtype 1 nor the HIV coinfection status. Conclusions: In this cohort of HCV and HIV/HCV coinfected patients, the natural strains of the NS3 protease domain related to resistance to HCVPI were well conserved. There is no influence of the anti-HIV PI therapy on the mutation rate in the NS3 protease. This finding could have implication for monitoring of the patients receiving anti-HCV PIs.

1205 MICROENVIRONMENTAL REGULATION OF SINOISODAL ENDOTHELIAL CELL PHENOTYPE

Sandra March1, Elliot E. Hui1, Sangeeta N. Bhatia1,2; 1Health Sciences and Technology / Electrical Engineering and Computer Science, Massachusetts Institute of Technology, Cambridge, MA; 2Medicine, Brigham and Women’s Hospital, Boston, MA

Liver Sinusoidal Endothelial Cells (LSEC) are distinct from other vascular endothelial cells (EC) present in other tissues in their structural and functional phenotypic characteristics. For example, in contrast to other EC, LSEC display fenestrations, have low or absent expression of PECAM-1, and in rat tissue, they distinctively express the specific surface marker SE-1. Interestingly, these phenotypic characteristics are lost over time when LSEC are placed in culture. Since phenotypic maintenance is
critical to the development of accurate in vitro models and tissue engineered constructs, this study set out to examine the effect of various microenvironmental stimuli, such as tailoring of the extracellular matrix (ECM) and co-culture with supportive cell types, on LSEC phenotype. Methods: Immunohistochemistry and Western blotting were used to characterize expression of the specific EC markers RECA, SE-1, PECAM and AcLDL in isolated primary rat LSECs cultured under the following conditions: a) on the different ECM proteins including, Collagen-I, Fibronectin, Laminin, and Collagen-IV; b) with various combinations of supportive cells, using the micromechanical reconfigurable culture method (PNAS 104:5722;2007) to enable tracking of individual cell types, separation into pure populations for analysis, and deconvolution of contact-mediated versus soluble signals; and c) in the presence of the tyrosine phosphatase inhibitor, orthovanadate (OV). Results: We documented a decrease in the expression of SE-1 and increase expression of PECAM-1 when LSEC are placed in culture; and an effect of specific ECM components on the levels of expression of SE-1 was observed, suggesting a role of ECM in modulating LSEC phenotype. Significantly, SE-1 expression could be maintained for longer periods through co-culture—up to 14 days in the optimal configuration involving co-cultivation with both hepatocytes and fibroblasts. The data also suggest that direct contact between LSECs and support cells is not necessary. To begin to gain a mechanistic insight into these observations, we investigated the role of tyrosine phosphorylation of cellular proteins in maintaining LSEC phenotype since it has previously demonstrated that OV inhibited LSEC apoptosis (AJP 168:1097; 2006). We found that SE-1 expression was strongly maintaining at day 3 when they were cultured in the presence of OV, suggesting that a decrease in protein phosphorylation is involved also in the loss of the phenotype. Conclusions: This study has identified novel microenvironmental regulators of the LSEC phenotype, which should be important for the development of better in vitro models of liver tissue.

1206 DEVELOPMENT AND CHARACTERIZATION OF MICROSCALE MODELS OF RAT AND HUMAN LIVERS
Salman Khetani1, Sangeeta N. Bhatia1,2; 1Health Sciences and Technology / Electrical Engineering and Computer Science, Massachusetts Institute of Technology, Cambridge, MA; 2Medicine, Brigham and Women’s Hospital, Boston, MA

Tissue function depends on hierarchical structures that extend from single cells to functional subunits. Conventional cell culture disperses tissues into single cells while neglecting higher-order processes. The convergence of semiconductor-driven microtechnology with the biomedical arena now allows fabrication of microscale tissue subunits towards functionally improving in vitro models. In the case of the liver, isolated hepatocytes are typically randomly distributed onto extracellular matrix without precise control over architecture and cell-cell interactions, which are known to impact hepatic functions. We sought to use microtechnology and heterotypic interactions between hepatocytes and nonparenchymal cells to create functionally robust, microscale models of rat and human livers. Methods: Primary rat hepatocytes were isolated from Lewis rats via collagenase perfusion while human hepatocytes were purchased from registered vendors. Soft lithography was used to generate micropatterned collagen domains in multi-well plates. The dimensions of collagen domains (500um circular diameter, 1200um center-to-center spacing) were empirically optimized to provide maximal hepatic functions via the balance of homotypic (hepatocyte-hepatocyte) and heterotypic (hepatocyte-fibroblast) interactions. Hepatocytes formed confluent clusters on collagen domains and were surrounded with fibroblasts shown to induce liver-specific functions. Micropatterned co-cultures were characterized for liver-specific gene expression (Affymetrix) and measurement of surrogate markers for diverse classes of liver functions (protein synthesis, nitrogen metabolism, detoxification). Results: Hepatocytes in our system retained in vivo-like morphology, expressed liver genes at levels highly similar to fresh hepatocyte controls, metabolized compounds using active Phase I/II enzymes, secreted diverse liver-specific products (albumin, urea), and displayed functional bile canaliculi for several weeks (4-6 for human, 10-12 for rat) in vitro. Micropatterned co-cultures outperformed conventional models (collagen sandwich, Matrigel overlay, random co-cultures) with regards to both magnitude of functions and longevity of cultures. We also quantified drug-drug interactions and toxicity of several clinical hepatotoxins in our system and found good qualitative correlation with in vivo findings. Conclusions: We utilized microtechnology to develop models of rat and human livers which remain functional for several weeks. In the future, improved models of liver tissue may be used for fundamental investigations of liver physiology and disease, cell-based therapies and toxicity screening in drug development.

1207 SWELLING-INDED TRAFFICKING OF ACTIN-COATED VESICLES AND CONTROL OF HEPATOCYTOPLIAL VOLUME REGULATION BY MYOSIN LIGHT CHAIN KINASE
Elisabeth T. Barfod1, Ann L. Moore2, Steven D. Lidofsky1,2; 1Pharmacology, University of Vermont, Burlington, VT; 2Medicine, University of Vermont, Burlington, VT

Physiological hepatocellular swelling stimulates vesicular exocytosis, which is exemplified by delivery to the plasma membrane of bile salt and other organic anion transporters to promote bile flow and volume recovery. Such vesicular trafficking, in part, requires an organized actin cytoskeleton and is regulated by myosin motors. However, since cell swelling evokes substantial dismantling of the actin cytoskeleton, it is unknown how such trafficking is regulated under these conditions. To address this, we performed live imaging of HTC hepatoma cells that expressed a green fluorescent protein (GFP) fusion of actin. In response to swelling produced by hypotonic exposure, the cortical actin cytoskeleton became less organized with fewer microfilaments, and actin puncta appeared from tubulovesicular structures in the cell interior and moved outward. Some puncta moved along filaments and then by apparent actin dynamics, we imaged cells expressing a red fluorescent protein (RFP) actin fusion with GFP fusions of other proteins. The fusion of actin-coated vesicles associated with known regulators of trafficking and actin dynamics, we imaged cells expressing a red fluorescent protein (RFP) actin fusion with GFP fusions of other proteins. The
RFP–actin-labeled puncta colocalized and moved with GFP fusions of cortactin, the Rho GTPase Cdc42, as well as with the Cdc42 activator Vav2. Because myosin light chain kinase (MLCK) has been implicated as a regulator of vesicular trafficking and of cell volume control, we tested whether it influenced these processes in HTC cells. Hypotonic swelling in the presence of the selective MLCK inhibitor ML7 (10 uM) produced enlarged intracellular actin structures that appeared to result from vesicle fusion and trapping, and ML7 attenuated cell volume recovery by approximately 60%. These data support the hypothesis that MLCK and, by implication, myosin motors regulate swelling-induced trafficking of actin-coated vesicles. Regulation of trafficking of such vesicles by MLCK is likely to be critical for targeting key signaling proteins, such as cortactin, Vav2, and Cdc42 to the cell cortex to coordinate cytoskeletal reorganization during volume recovery.

OVEREXPRESSION OF CYP2E1 IN LIVER INCREASES INSULIN RESISTANCE AND INHIBITS INSULIN SIGNALING IN AN ANIMAL MODEL OF NASH
Elango Kathirivel1,2, Philip T. Chen2, Kanginthev Morgan1,2, Samuel W. French2, Timothy R. Morgan1,2; 1Department of Medicine/Gastroenterology, VA Long Beach Healthcare System, Long Beach, CA; 2Medicine, University of California, Orange, CA;

BACKGROUND: Down regulation of insulin signaling, characterized by increased serine phosphorylation of IRS-1 and decreased phosphorylation of Akt and of FoxO1a, has been reported in hepatocytes overexpressing CYP2E1 in vitro. AIM of our study was to evaluate insulin signaling pathways in an animal model of CYP2E1 overexpression and insulin resistance/NASH. METHODS: Rodent chow containing high fat (20% of calories from fat) was fed to male CYP2E1 transgenic (Tg) and to non-transgenic (n-Tg) mice for 9 months (n=7 in each group). Tg mice contain human CYP2E1 cDNA under control of the mouse albumin enhancer-promoter and overexpress CYP2E1 in the liver. Fasting serum insulin and glucose were measured a week prior to euthanasia. Mice were allowed free access to food until euthanasia. Liver pathology was evaluated and mRNA expression of IRS-1, IRS-2, Akt and phosphorylated IRS-1, IRS-2, Akt, GSK3 and FoxO1a protein content were measured by immunoprecipitation and western blotting. RESULTS: Tg mice had increased liver injury (fat, pathology, ALT) and insulin resistance as measured by significantly increased fasting serum insulin and glucose levels. mRNA expression of IRS-1 was increased 13-fold in Tg mice although the total amount of IRS-1 protein was similar in both groups. Tyrosine phosphorylation of IRS-1 was decreased by 40% in Tg mice although serine phosphorylation at 307 and 635 was unchanged. mRNA expression and protein content of total IRS-2 and total Akt were similar in the two groups, while p-Akt was 30% lower in Tg than in n-Tg mice. Total GSK3 was similar in both groups, while p-GSK3 was decreased by 40% in Tg mice. We found a 2-fold decrease in the amount of phosphorylated (inactivated) FoxO1a in Tg mice, associated with a 2-fold increase in the mRNA expression of PEPCK. CONCLUSIONS: In an animal model of CYP2E1 overexpression and NASH, we found increased insulin resistance, as demonstrated by increased fasting insulin and glucose. Insulin signal transduction was decreased in CYP2E1 Tg mice, as shown by decreased tyrosine phosphorylation of IRS-1, Akt and GSK3. Importantly, in Tg mice phosphorylation (inactivation) of FoxO1a was decreased and expression of PEPCK was increased, consistent with increased gluconeogenesis. This experiment demonstrates several defects in insulin signal transduction in vivo in the setting of increased CYP2E1 expression, and further supports a role for CYP2E1 in insulin resistance and NASH.

POST-TRANSLATIONAL MODIFICATION OF HEPATIC SCAVENGER RECEPTOR CLASS B, TYPE I AND CHYLOMICRON METABOLISM IN A MOUSE MODEL
Tao Fu1, Marc S. Elias1, Nishath Quader1, Jayme Borensztajn2; 1Medicine/Hepatology, Northwestern University, Chicago, IL; 2Pathology, Northwestern University, Chicago, IL

BACKGROUND: The liver plays a pivotal role in post-prandial lipoprotein metabolism. Remnants of chylomicrons are cleared from circulation exclusively by the liver by receptor-mediated mechanisms that are both apoE-dependent and apoE-independent. Recent work with mice showed that: a) the hepatic scavenger receptor class B type I (SR-BI), which functions as a receptor for high-density lipoproteins, is also a receptor for chylomicron remnants in a manner independent of apoE; b) activation of peroxisome proliferator-activated receptor alpha (PPARalpha) elicits post-transcriptional or post-translational down-regulation of SR-BI protein in wild-type and apoE-deficient mice; c) treatment of apoE-deficient mice with PPARalpha agonists inhibits the SR-BI-mediated uptake of remnants by the liver. We investigated the mechanism underlying PPARalpha-mediated post-translational regulation of hepatic SR-BI which affects chylomicron metabolism. Methods: Homozygous female apoE-deficient mice (5 mice/group) on C57BL/6J background (8-12-week-old) were treated with or without 0.05% (w/w) ciprofibrate for 30 days. The plasma was then collected for the lipoprotein profile analysis with FPLC separation, measurement of mass contents of cholesterol and triglycerides, and Western blot assay of apolipoproteins B100/B48. Livers were harvested for histochemistry analysis to detect the distribution of SR-BI; for Western blot assay for SR-BI protein expression; and for biochemical analysis of post-translational modification of SR-BI by glycosylation. Results: Treatment of apoE-deficient mice with ciprofibrate produced a 3-4-fold increase of total cholesterol content and apoB48-rich chylomicron remnants in the plasma. Western blot analysis with an antibody against the c-terminal of murine SR-BI revealed that the fibrate treatment produced multiple bands (from 82 kDa to 54 kDa) of SR-BI in liver homogenate samples. N-glycosidase F treatment of liver homogenate from apoE-deficient mice and Western blot assay for SR-BI demonstrated that fibrate treatment inhibited N-glycosylation of SR-BI. Immunohistochemistry analysis showed that fibrate induced an increased expression of SR-BI protein in the cytosol of hepatocytes, but decreased its expression in the plasma membrane. Cessation of the fibrate treatment reversed both accumulation of chylomicron remnants and reduction of 82 kDa SR-BI in the membrane fraction. Conclusion: PPARalpha agonist-induced post-translational modification of hepatic SR-BI decreases the presence of SR-BI on the surface of hepatocytes, and therefore, interferes with chylomicron remnant metabolism.

Hepatocarcinogenesis.

We found upregulation of Wnt3 expression in human hepatocellular carcinoma (HCC) tissues compared to adjacent peritumoral tissues, whereas the expression level of Wnt11 was downregulated in HCC. Activation of the canonical Wnt signaling is often to be observed in HCC and Wnt3 is a major Wnt ligand to activate the canonical pathway in HCC. In contrast, the role of Wnt11, which is an activator for the non-canonical Wnt signaling pathway in hepatocarcinogenesis is completely unknown. In the present study, we investigated the effects of Wnt11 on the canonical Wnt signaling through the activation of the non-canonical pathway in HCC. Methods: We used FOCUS and Huh7 HCC cells overexpressing Wnt11 by transient and stable transfection. The canonical Wnt signaling was examined by Westernblotting, immunofluorescencstaining, and β-catenin-mediated T-cell factor (TCF) reporter assays. The non-canonical signaling was evaluated by Protein Kinase C (PKC) kinase assay, Rho pull down assay, and immunoblot analysis for CamKII and cJUN activity. A MTS assay was used for evaluation of cell proliferation rate. Results: Overexpression of Wnt11 in HCC cells decreased the total expression and nuclear localization of β-catenin compared to control cells. The levels of phospho-β-catenin, leading to β-catenin proteasomal degradation, increased in Wnt11 overexpressing cells. The β-catenin-mediated TCF transcriptional activity was also reduced by 50% in Wnt11 overexpressing cells. Knockdown of Wnt11 using RNA interference in Wnt11 overexpressing FOCUS cells (FOCUSWnt11) restored β-catenin expression and TCF transcriptional activity confirming that Wnt11 antagonized the Wnt/β-catenin pathway. In the non-canonical Wnt signaling pathway, overexpression of Wnt11 activated PKC kinase and Rho kinase activities and a PKC specific inhibitor, not a Rho inhibitor, reduced phosphorylation of β-catenin indicating that PKC was responsible for β-catenin phosphorylation in FOCUSWnt11 cells. Finally HCC cell proliferation rate was reduced in FOCUSWnt11 compared to control cells. Conclusion: Wnt11 stimulated PKC and Rho activity, and the activation of PKC was involved in the inhibition of the canonical Wnt signaling pathway, leading to the growth suppression in HCC cell lines, suggesting that distinct Wnt signaling pathways may be capable of crosstalk, leading to functional antagonism in hepatocarcinogenesis.

Wnt11 inhibits the canonical Wnt pathway through the PKC-mediated β-catenin phosphor-ylation in human hepatoma cells

Takashi Toyama, Han Chu Lee, Jack R. Wands, Miran Kim; Liver Research Center, Rhode Island Hospital and The Warren Alpert Medical School of Brown University, Providence, RI

Background and Aims: Wnt signaling plays an important role in early embryonic development and carcinogenesis. Recently we identified Wnt3 and Wnt11 as major Wnt ligands among 19 Wnt family members in human hepatoma cells. Furthermore, we found upregulation of Wnt3 expression in human hepatocellular carcinoma (HCC) tissues compared to adjacent peritumoral tissues, whereas the expression level of Wnt11 was downregulated in HCC. Activation of the canonical Wnt signaling is often to be observed in HCC and Wnt3 is a major Wnt ligand to activate the canonical pathway in HCC. In contrast, the role of Wnt11, which is an activator for the non-canonical Wnt signaling pathway in hepatocarcinogenesis is completely unknown. In the present study, we investigated the effects of Wnt11 on the canonical Wnt signaling through the activation of the non-canonical pathway in HCC. Methods: We used FOCUS and Huh7 HCC cells overexpressing Wnt11 by transient and stable transfection. The canonical Wnt signaling was examined by Westernblotting, immunofluorescencstaining, and β-catenin-mediated T-cell factor (TCF) reporter assays. The non-canonical signaling was evaluated by Protein Kinase C (PKC) kinase assay, Rho pull down assay, and immunoblot analysis for CamKII and cJUN activity. A MTS assay was used for evaluation of cell proliferation rate. Results: Overexpression of Wnt11 in HCC cells decreased the total expression and nuclear localization of β-catenin compared to control cells. The levels of phospho-β-catenin, leading to β-catenin proteasomal degradation, increased in Wnt11 overexpressing cells. The β-catenin-mediated TCF transcriptional activity was also reduced by 50% in Wnt11 overexpressing cells. Knockdown of Wnt11 using RNA interference in Wnt11 overexpressing FOCUS cells (FOCUSWnt11) restored β-catenin expression and TCF transcriptional activity confirming that Wnt11 antagonized the Wnt/β-catenin pathway. In the non-canonical Wnt signaling pathway, overexpression of Wnt11 activated PKC kinase and Rho kinase activities and a PKC specific inhibitor, not a Rho inhibitor, reduced phosphorylation of β-catenin indicating that PKC was responsible for β-catenin phosphorylation in FOCUSWnt11 cells. 1211 Negative feedback regulation of β-catenin signaling by the microenvironment through a frizzled-like module in the extracellular matrix of hepatocellular carcinoma

Orlando Musso1, Ismail Hendaooui2, Elise Lavergne1, Harri Elamaa3, Nathalie Theret1, Delphine Quelard1, Bruno Turlin1, Taina Pihlajaniemi1, Bruno Clement1; 1INSERM U620, Rennes, France; 2MEDICAL BIOCHEMISTRY, UNIVERSITY OF OULU, OULU, Finland

Collagen XVIII (C18) is an extracellular matrix component and a plasma protein secreted by hepatocytes. Of its variants contains a protein module of unknown function homologous to secreted frizzled-related proteins (SFRPs), which are inhibitors of the Wnt/β-catenin pathway, hence named frizzled (FZC18). The expression of the C18 variant containing FZC18 was assessed in 19 normal livers, 54 hepatocellular carcinomas (HCCs) and 49 matching non tumor areas. Increased FZC18 mRNA expression was associated with liver fibrosis (p<0.0001) and small (≤2 cm), well-differentiated HCCs (p=0.02). Immunohistochemistry was performed on serial sections of normal, cirrhotic liver and HCCs with anti-FZC18, anti-β-catenin and anti-glutamine synthetase (GS) antibodies. GS is a downstream target of β-catenin and a marker of activating β-catenin mutations in HCC (Oncogene, 26:7774). In normal liver, FZC18 epitopes were predominantly periportal, contrasting with the well-characterized pericentral vein localization of GS (Developmental Cell, 10: 759), indicating that FZC18 is associated with liver zones of low β-catenin pathway activation. In HCCs, FZC18 was negatively correlated with GS (r=−0.42; p=0.02; n=24) and cytoplasmic β-catenin staining (r=−0.47; p=0.02; n=23). Conversely, FZC18 was positively correlated with membranous β-catenin staining (r=0.67; p<0.001; n=23). As expected, nuclear and cytoplasmic β-catenin staining were highly correlated (r=0.89; p<0.001; n=23), as well as GS and nuclear (r=0.74; p<0.001; n=23) or cytoplasmic β-catenin (r=0.63; p<0.001; n=23). Moreover, the human HCC cell line Huh-7 (wild-type β-catenin and basal pathway activity) was transfected with a constitutively activated form of β-catenin (Δ29-48), which increased β-catenin pathway activity by 10 folds in a β-catenin/TCF reporter assay, as well as total and non phosphorylated β-catenin, GS and cyclin D1 protein levels. Cotransfection of FZC18 cDNA decreased β-catenin activity, including total and non phosphorylated β-catenin, together with GS and cyclin D1 proteins to normal levels. These findings indicate that the FZC18 module of collagen XVIII down-regulates β-catenin pathway activity in HCC. Thus, the microenvironment, which contains frizzled-like modules entrapped within the extracellular matrix, such as FZC18 and SFRPs, may negatively regulate the Wnt/β-catenin pathway and thus impede the progression of hepatocellular carcinoma.

1212 Inactivation of caspase-8 affects hepatocyte proliferation after partial hepatectomy in mice

Julia Freimuth1, Dieter Riehmsacher2, Christian Trautwein1, Christian Liedtke1; 1Medicine III, University Hospital Aachen, Aachen, Germany; 2Centre for Molecular Neurobiology, Hamburg, Germany

The cytokine TNF plays a crucial role during early liver regeneration after partial hepatectomy (PH) triggering signaling path-
ways for cell proliferation (via NF-kB), activation of cJun N-terminal kinases (JNK) and apoptosis through caspase-8 activation. The aim of this study was to investigate the potential role of caspase-8 during liver regeneration. PH was performed in hepatocyte-specific caspase-8 knock-out (casp8Δhepa) mice and wildtype (WT) controls. Analysis of hepatocyte proliferation was determined by BrdU-staining from liver cryosections. Expression of cell cycle markers for G1- (cyclin D), G1/S- (cyclin E) and S-phase (cyclin A) were analysed by real-time PCR and immunoblotting. Histone H3 phosphorylation was used as a marker for M-phase progression. Phosphorylation and nuclear translocation of c-jun in hepatocytes was displayed using as a marker for M-phase progression. Phosphorylation and nuclear translocation of c-jun in hepatocytes was displayed through immunofluorescence microscopy. Apoptosis in the regenerating liver was monitored by TUNEL assay. Following PH, cyclin D1 expression in casp8Δhepa mice reached maximum levels 10 hours (h) earlier compared to controls with a peak already 30h after surgery. BrdU incorporation exhibited a 4 fold higher increase in casp8Δhepa mice 30h after PH and a prolonged S-phase compared to controls. Additionally, first expression of cyclin E and A was detected earlier in casp8Δhepa mice (30h post PH) compared to WT animals and reached its peak 12h before the control group (36h compared to 48h after PH). At time points 60h and later post surgery proliferation decreased within both groups to a similar level. M-phase analysis revealed higher number of mitotic cells in casp8Δhepa mice compared to WT animals in a time frame between 30h and 60h after surgery. Seven days after PH relevant levels of apoptosis were detected in WT mice, but not in casp8Δhepa animals indicating that apoptotic mechanisms are relevant for terminating liver regeneration. To further investigate the mechanism leading to earlier onset of cell cycle progression in casp8Δhepa mice, we analysed activation of c-jun, which is a known transactivator of cyclin D expression. Interestingly, already 30 minutes after surgery we observed phosphorylation and nuclear translocation of c-jun in casp8Δhepa mice, whereas first detection in WT animals was evident after 2 hours. Our data demonstrate that depletion of caspase-8 leads to an accelerated onset of liver regeneration after PH. We conclude that rapid activation of c-jun in casp8Δhepa mice contributes to earlier induction of cyclin D and subsequent cell cycle progression.

IGF-II IS A GROWTH FACTOR TO HEPATOBLASTOMA AND HEPATOCELLULAR CARCINOMA VIA PHOSPHATIDYL INOSITOL 3 KINASE AS A TARGET OF MOLECULAR THERAPY

Minoru Tomizawa, Osamu Yokosuka; Department of Medicine and Clinical Oncology, Chiba University Graduate School of Medicine, Chiba City, Japan

Hepatoblastoma (HBL) arises in livers of infants younger than 2 years of age, while hepatocellular carcinoma (HCC) in adults. Insulin-like growth factor (IGF-II), deeply involved in proliferation and differentiation, is more expressed in tumor than surrounding non-tumor of HBL and HCC. IGF-II is highly expressed in the blood of HBL patients. IGF-II binds IGF-I receptor (IGF-IR), and its stimulation is transferred via phosphatidyl inositol (PI) 3 kinase or mitogen activated protein (MAP) kinase. We addressed the possibility that IGF-II is a growth factor of HBL and HCC and its signaling pathway. Growth of HCC cell lines [HLE, HLF, PLC Huh-7, Hep3B] and HBL cell lines [Huh-6, HepG2] were analyzed with 3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium inner salt (MTS) assay. MTS is bioreduced by cells into a colored formazan product that reduces absorbance at 490nm. MTS assay was performed after 72 hours culture with IGF-II (0, 2, 20, 200 ng/ml) following 24 hours of serum free culture. Protein was isolated after 48 hours serum free culture for Western blot analysis with IGF-IR antibody. LY294002 (50 μM), a specific inhibitor of PI3 kinase or PD98059 (20 μM), a specific inhibitor of MAP kinase, was added with IGF-II (200 ng/ml) for 72 hours after 24 hours serum free culture, and cell growth was analyzed with MTS assay. P value <0.05 was accepted as statistical significance with one-factor ANOVA. Cell growth was not changed between 200 ng/ml of IGF-II and 0 ng/ml in HLE (1.03) and HLF (1.09), poorly differentiated HCC (n=9). In well differentiated HCC, cell number was not changed in PLC (1.07) and Huh-7 (1.00), while elevated in Hep3B (1.47, P<0.05) (n=9). Cell number was elevated in Huh-6 (1.39, P<0.05) and HepG2 (2.00, P<0.05), well differentiated HBL cell lines (n=9). IGF-IR was expressed in all cell lines. When LY294002 was added, cell growth was suppressed for all cell lines compared as with IGF-II only (0.22-0.43) (n=3). Cell growth was suppressed with PD98059 with IGF-II as compared with IGF-II only in HepG2 (0.35, P<0.05) while it was not changed significantly in the other cell lines (n=3). It was clarified that IGF-II activated proliferative potential of well differentiated HBL and HCC cell lines via IGF-IR followed by PI3 kinase. It was hypothesized that poorly differentiated HCC proliferate independently of a growth factor. Phosphorylation of IGF-IR might differ among cell lines, which varied the proliferative response to IGF-II. In the future, we will focus on phosphorylation of IGF-IR. It was suggested that PI3 kinase was a suitable candidate for molecular therapy to HCC as well as HBL.

PTEN ASSOCIATION WITH PI3K85α SUBUNIT IS A NEGATIVE REGULATORY MECHANISM FOR INSULIN SIGNALING IN THE LIVER

Jiman He, Suzanne de la Monte, Jack R. Wands; Liver Research Center, Rhode Island Hospital and The Warren Alpert Medical School of Brown University, Providence, RI

Background: Insulin is an important growth factor for the normal liver. In hepatocellular carcinoma (HCC) there is often constitutive activation of insulin/IGF-1 signaling through insulin receptor substrate-1 (IRS-1). In this context, signals are sent via the insulin/IRS-1/PI3K/Akt/GSK3β pathway thus promoting hepatocyte survival since the functional consequences are inhibition of apoptosis. The mechanisms of how insulin signaling is regulated with respect to liver growth is not clear. Recent preliminary studies suggest that PTEN may associate with the PI3K85α subunit which would negatively regulate PI3K/Akt signaling leading to insulin resistance both in vivo and in vitro. The present study was designed to evaluate how the insulin signal is attenuated as it relates to downstream growth effects and survival signals in liver. Methods: HuH 7 cells were cultured in DMEM in 10% fetal calf serum. After an overnight period of serum starvation, insulin stimulation (0.075U/ml) was provided for 40 min. We assessed Akt phosphorylation/dephosphorylation at different time points as a downstream indicator of insulin signaling through PI3. In addition, we evaluated the physical association between PTEN and the PI3K85α subunit by co-immunoprecipitation experiments. To further clarify the role of PTEN, siRNA knockdown experiments of PTEN gene expression
were performed to enhance insulin signaling through PI3K. Finally, in vivo experiments were performed in mice acutely treated with an I.P. injection of insulin followed by euthanization. Liver samples were tested for p-Akt activity and the association of PTEN with PI3K85α. Results: We observed that insulin stimulation of HuH7 cells rapidly activated the PI3K/Akt signal transduction cascade as revealed by a time dependent increase in p-Akt. Within 5 - 10 min of insulin exposure, a negative regulatory effect of PTEN was evident as shown by a rapid association with PI3K85α both in vitro and in vivo. The association of PTEN with PI3K85α revealed a similar time course to the activation and deactivation of p-Akt. Therefore, this rapid association of PTEN with PI3K85α represents a negative regulatory mechanism to attenuate the insulin signal. More important, silencing of the PTEN gene by siRNA prolonged the activation of p-Akt which further demonstrated its important role in insulin homeostasis. Conclusions: These studies suggest that the PI3K85α subunit is a natural substrate for PTEN and the interaction between these two proteins provide an important negative regulator function for insulin signaling in the liver.

FARNESOID X RECEPTOR (FXR) REGULATES RECK EXPRESSION
Helen B. Hartman1, Wenyan Zhong2, Douglas C. Harnish1, Paige E. Mahaney3, Mark J. Evans1; 1Cardiovascular and Metabolic Diseases Research, Wyeth, Collegeville, PA; 2Biological Technologies, Wyeth, Collegeville, PA; 3Chemical and Screening Sciences, Wyeth, Collegeville, PA

Elevated expression of RECK (reversion-inducing cysteine-rich protein with Kazal motifs) is a favorable prognostic marker in hepatocellular carcinoma, potentially due to the ability of RECK to inhibit tumor cell invasion and metastatic activities. Here we demonstrate that the farnesoid X receptor (FXR) induces RECK expression. Oral administration of a potent synthetic FXR agonist, FXR-450, for seven days elevated RECK expression several fold in the liver of multiple mouse strains. The basal liver expression of RECK was reduced in FXRKO mice, and FXR-450 did not increase RECK expression in FXRKO mice. A single oral dose of FXR-450 significantly increased RECK expression in the liver within 2 hours, suggesting a direct induction. RECK expression was also rapidly induced in cultured primary mouse hepatocytes and in AML-12 hepatocytes by the FXR agonists GW4064 and FXR-450. The selective FXR antagonist WAY-396551 blocked these inductions and reduced basal RECK expression. An active FXR response element was localized within the first intron of the RECK gene. Finally, FXR-450 also induced RECK expression in human primary hepatocytes. Together these results suggest FXR is a novel regulator of RECK and point to the potential therapeutic use of FXR agonists in tumors expressing FXR such as hepatocellular carcinoma.

Aims: Hepatocellular carcinoma (HCC) is one of the most lethal malignancies worldwide and no effective chemotherapeutic or -preventive treatments are currently available. We previously showed that specific cyclooxygenase (COX)-2 inhibition activates intrinsic as well as extrinsic apoptotic pathways in HCC cells and induces apoptosis in an in vivo model of HCC [1-3]. We also showed that the neoplastic effects of COX-2 overexpression can predominantly be ascribed to PGE2, which acts via differentially regulated EP-receptors (EP1-4). This study was designed to analyze the expression of potential novel targets downstream of COX-2 (PGE2-synthases (mPGES-1 and -2) and EP1-4) in HCCs and to evaluate the potential of EP-receptor-antagonism as a new approach to the treatment of HCC. Methods: Using tissue micro-arrays (TMAs) comprising a total of 14 control livers, 17 liver cirrhoses, 22 premalignant dysplastic nodules (DNs) and 162 HCCs with different histological grades, the expression of COX-2, mPGES-1 and -2 and EP1-4 were analyzed. Western immunoblot analyses were performed to confirm the expression in HCC cell lines. The effects of EP1-4-receptor antagonism on cell viability and apoptosis were investigated using MTT-assays and FACS-analyses of propidium iodide-stained nuclei. Results: COX-2 and EP1-4 were expressed in all HCC cell lines and tissues. COX-2 expression was highest in DNs and declined with loss of HCC-differentiation, whereas a converse expression of EP1-3, respectively an inverse expression of mPGES-1 and -2 with high expression in poorly-differentiated HCCs was found in comparison to COX-2. Selective EP1- and EP3-antagonists significantly reduced the viability of HCC cells in a dose-dependent manner (up to 80% reduction), which was associated with apoptosis induction. In contrast, selective EP2- and EP4-receptor antagonists elicited no marked effects. Conclusion: Our TMA-results indicate that mPGES-1 and -2 as well as EP1-3 might represent potential new targets. Furthermore, our data suggest that PGE2-induced neoplastic effects are, at least in part, mediated via EP1- and EP3-receptors in HCC cells, implying that selective antagonists of these EP-receptors may provide a novel therapeutic approach to the treatment of HCCs. EP-receptor signaling depends largely on the cellular context. Thus, selective modulation of EP-receptors might exert fewer side-effects compared to a general abrogation of prostaglandin synthesis with COX-inhibitors. 1. Kern MA, Haugg AM, et al. 1217 CONDITIONAL ABLATION OF C-FLIP RENDERS HEPATOCYTE MORE SENSITIVE TOWARDS CD95 MEDIATED APOPTOSIS IN VIVO

Marcus Schuchmann1, Daniel Sammet1, Jörn M. Schattenberg1, Jürgen Siebler1, You-Wen He2, Peter R. Galle1; 1I. Department of Medicine, University of Mainz, Mainz, Germany; 2Department of Immunology, Dukes University, Durham, NC

Hepatocytes are highly susceptible to CD95 induced apoptosis and receptor mediated apoptosis is of particular importance in many liver diseases. CD95 (Fas) and CD120a (TNF-R1) are the most prominent cell death receptors in this context. Receptor aggregation upon ligand binding and subsequent recruitment of the adapter molecules FADD is a prerequisite for DISC formation, caspase-8 activation and subsequent initiation of the apoptotic machinery. The caspase-8 homologue FLIP exerts antiapoptotic function and was shown to be involved in maturation and CD95 mediated apoptosis of T-cells (Zhang and He, JEM, 2005). Here, we demonstrate that FLIP is involved in regulation of CD95 induced liver injury in vivo. Method: We generated mice conditionally lacking c-FLIP by crossing mice harboring a loxP flanked exon 1 of flip with transgenic mice expressing Cre recombinase under the control of the albumin promoter. Results: AlbCre-flip-/- mice were significantly more sensitive towards CD95 induced liver failure. Liver function tests of 8-week-old wildtype (n=12) and albCre-flip-/- (n=7) mice were evaluated 3 hours after intra venous injection of 0.15 ug/g of anti-CD95 (Jo2) antibody: The flip-/- mice showed significantly higher numbers for ALT (2237 vs. 259) and AST (2015 vs. 119 IU/L). This was accompanied by higher relative activities for caspase-3 (33840 vs. 2980), caspase-8 (4675 vs. 3507) and caspase-9 (1534 vs. 756 rel. Units) in whole liver lysates. In line with these observations, histology in H/E staining showed more apoptotic cells in the anti-CD95 treated albcre-flip-/- mice. In conclusion, our data demonstrate a specific role for c-FLIP in the regulation of CD95 mediated apoptosis of hepatocytes in vivo.

1218 MICRORNA-370 REGULATES INTERLEUKIN-6 DEPENDENT P38 MAP KINASE SIGNALING IN HUMAN CHOLANGIOCARCINOMA

Fanyin Meng1,2, Hania Wehbe-Janek2, Roger Henson2, Heather Smith2, Tushar Patel1,2; 1Department of Internal Medicine, Ohio State University Medical Center, Columbus, OH; 2Scott & White Clinic, Temple, TX

Background & Aims: The inflammatory cytokine Interleukin-6 (IL-6) is over-expressed in cholangiocarcinoma and contributes to tumor growth by aberrant p38 MAP kinase signaling. Enforced expression of IL-6 can alter the expression of microRNAs (miRNAs), non-coding RNAs that reduce the expression of target genes. Thus, our aims were to characterize the role of aberrantly expressed miRNA in the modulation of p38 MAP kinase signaling by IL-6 in human cholangiocarcinoma cells. Methods: MzChA-1 and KMCH-1 cholangiocarcinoma cells were stably transfected to over-express IL-6. miRNA expression profiling was performed in normal and malignant cholangiocytes using a hybridization based microarray. The expression of selected mature miRNA was verified by real-time PCR assay. The effect of selected miRNA on cell growth was assessed using precursor miRNA to increase cellular expression, or miRNA specific antisense oligonucleotides to decrease miRNA expression. Cell proliferation was quantitated using MTS assay and protein expression measured by quantitative immunoblot analysis. Results: The expression of MAP3K8, an upstream kinase regulator of p38 MAPK was increased in MzChA-1 cells by 62 ± 12% and in KMCH-1 cells by 51 ± 7% relative to normal human cholangiocytes. Using target prediction algorithms, MAP3K8 was identified as a potential target for microRNA mir-370. MAP3K8 was experimentally verified as a direct target of mir-370 by dual luciferase reporter assay. The expression of mature mir-370 was decreased in both Mz-ChA-1 and KMCH-1 cells compared to normal human cholangiocytes. In IL-6 over-expressing cells, expression of mir-370 was decreased by 85 ± 7%, whereas that of MAP3K8 was increased by 105 ± 19%. Cell growth was not altered in normal human cholangiocytes transfected with mir-370 precursor. However, over-expression of mir-370 in Mz-ChA-1 cells decreased tumor cell proliferation by 31 ± 3% and moreover decreased expression of both MAP3K8 by 0.34 ± 0.11-fold and phosphorylated p38 MAP kinase by 0.45 ± 0.13-fold. In IL-6 over-expressing tumor cell xenografts, mir-370 expression was reduced by 87 ± 16%, while MAP3K8 and phospho-p38 MAPK were increased by 153 ± 22% and 87 ± 15%, respectively. Summary and Conclusions: These results identify for the first time that MAP3K8 is a biological target gene of miR-370. The modulation of expression of mir-370 and MAP3K8 provides a direct mechanism by which IL-6 over-expression can result in aberrant p38 MAPK signaling. These findings identify a novel mechanism by which oncogenic kinases can be aberrantly expressed and contribute to tumor growth in cholangiocarcinoma.

1219 IL-22 MAY BE INVOLVED IN LIVER REGENERATION VIA A STAT-3 SIGNALING PATHWAY AFTER 70% HEPATECTOMY

Xiaodan Ren, Lisa Colletti; Department of Surgery, University of Michigan, Ann Arbor, MI

Objective: Hepatocyte proliferation, triggered by partial hepatectomy, is an important component of liver regeneration. Recent studies have shown that IL-22 mediates inflammatory processes through IL-10 receptor β and/or IL-22 receptor α. In vitro studies have also demonstrated that IL-22 is also involved in cellular proliferation in other cell types. The goal of this study was to investigate the potential role of IL-22 in mouse liver regeneration after 70% hepatectomy. Methods: Partial hepatectomy or sham laparotomy was performed in C57BL/6 mice, animals were sacrificed in a kinetic fashion, and real-time PCR was used to measure hepatic levels of IL-22 and IL-22R after hepatic resection. Hepatocyte proliferation, as estimated by BrdU staining, and measurement of p-stat-3 levels by Western blot, was investigated in mice undergoing 70% hepatectomy or sham laparotomy after treatment with IL-22 antibody or IL-22 antigen. Results: These data show that IL-22 is upregulated within 6 hours of 70% hepatectomy, and significant increases in IL-22R are seen as early as 1 hour, with peak levels occurring 3 hours post-hepatectomy. Administration of exogenous IL-22 antibody 30 minutes before hepatectomy decreased hepatocyte proliferation at 48 hours post-hepatectomy and reduced stat-3 activation within 30 minutes of resection, as compared to mice receiving control IgG prior to hepatic resection. While exogenous administration of IL-22 antigen immediately before liver resection did not significantly change hepatocyte proliferation, this treatment did increase stat-3 acti-
Differential expression of discoid domain receptors in epithelial-mesenchymal transition

Hironori Koga1, Michiko Maeyama1, Sivakumar Ramadoss1, Selvendiran Karuppiah1, Takaoki Yoshida1, Osamu Hashimoto1, Mitsuhiko Abe1, Chikatoshi Yanagimoto1, Hiroto Kumemura1, Shinichiro Hanada1, Eitaro Taniguchi1, Takumi Kawaguchi1, Masaru Harada1, Takatu Torimura1, Hirohisa Yano2, Takato Ueno3, Shinichiro Hanada3, Eitaro Taniguchi1, Takumi Kawaguchi1, Michio Sata1; 1Division of Gastroenterology, Department of Medicine, Kurume University, Kurume, Japan; 2Dorothy M. Davis Heart and Lung Research Institute, The Ohio State University Medical Center, Columbus, OH; 3Department of Pathology, Kurume University, Kurume, Japan; 4Research Center for Innovative Cancer Therapy, Kurume University, Kurume, Japan

Repressors of E-cadherin, such as Snail, Slug, and Twist, cause "epithelial-mesenchymal transition (EMT)"; however, acquired features of the transformed cells are not fully understood. The aim of this study was to assess alterations in both the proliferative potential and the responsiveness to extracellular matrices (ECMs) in EMT. Methods: MDCK cells, the immortalized human hepatocyte cell line OUMS-29, and the clonally-identified sister hepatoma cell lines HAK-1A and HAK-1B were used in this study. EMT was induced by transfection of the Slug cDNA (FLAG-tagged), which was a kind gift from Professor Eric R. Fearon (University of Michigan Medical School). Cell proliferation was analyzed by flow cytometry and Western blot of the cell-cycle associated proteins. ECM-stimulated cell proliferation was examined by counting cells cultured on the following ECMs: type I collagen, type IV collagen, fibronectin, and laminin. Protein phosphorylation was detected by immunoprecipitation-Western using anti-tyrosine antibody. Results: Both the G1 and the G2/M arrest were found in the Slug-transfected cells, and the responsible molecules for the cell-cycle arrest were, at least in part, p21 and Wee1. Once in contact with type I collagen and fibronectin, Slug-transfected cells dramatically started to proliferate up to six-fold in cell number at day 5, in contrast to only two-fold increase in cell number in parental cells. Thus, we focused on the expression status of the collagen receptors including those of non-integrin types, and found a remarkable increase in the discoid domain receptor (DDR) 2 expression, in contrast to a significant decrease in the DDR1 expression, in Slug-transfected cells. The expression levels in β1 and αV/β3 integrins were not changed. The constitutive expression of DDR2 was predominantly found in HAK-1B, in comparison with HAK-1A, which resembled well differentiated hepatocellular carcinoma cells. Immunoprecipitated DDR2 protein in the lysate of the collagen-stimulated Slug-MDCK cells was phosphorylated, indicating that the Slug-induced DDR2 mediated "outside-in" signal. Conclusion: We found a cell-cycle arrest in Slug-transfected cells; however, contact with type I collagen clearly abolished the arrest and even promoted cell proliferation in these cells. The Slug-transfected cells predominantly expressed the non-integrin collagen receptor DDR2, which was also profoundly expressed in aggressive hepatoma cells. DDR2 may be a marker for EMT and play a role in mediating signal from type I collagen.

P53 is a specific molecular target of ursodeoxycholic acid in regulating apoptosis

Joana D. Amaral1, Rui E. Castro1, Susana Solâ1, Clifford J. Steer2-4, Cecilia Maria P. Rodrigues1; 1iMed.UL, Faculty of Pharmacy, University of Lisbon, Lisbon, Portugal; 2Department of Medicine, University of Minnesota Medical School, Minneapolis, MN; 3Department of Genetics, Cell Biology and Development, University of Minnesota Medical School, Minneapolis, MN

p53 plays an important role in regulating expression of genes that mediate cell cycle progression and/or apoptosis. In addition, we have previously shown that the hydrophilic bile acid ursodeoxycholic acid (UDCA) prevents TGF-β1-induced p53 stabilization and apoptosis in primary rat hepatocytes. Therefore, we hypothesized that p53 may represent an important target in bile acid-induced modulation of apoptosis and cell survival. Primary rat hepatocytes were cotransfected with plasmid DNA encoding wild-type or mutant p53 and a reporter gene construct that utilized the bax gene promoter to drive transcription of chloramphenicol acetyltransferase (CAT). Twelve hours prior to transfection, hepatocytes were pre-treated with either vehicle or 100 μM of UDCA. At 48 h post-transfection, hepatocytes were harvested for CAT ELISA and luciferase control assays. Cultures were also scored for apoptosis following Hoechst staining, and culture media used for viability assays. General caspase-3-like activity was determined in cytosolic protein extracts by enzymatic cleavage of the substrate. Nuclear, mitochondrial, and cytosolic fractions, or total proteins were also prepared and analyzed by immunoblotting. p53 DNA binding activity was evaluated in parallel experiments. Finally, immunofluorescence and immunoblotting were used to detect p53 cellular distribution. The results showed that UDCA reduced p53 transcriptional activity, thereby preventing its ability to induce Bax expression, mitochondrial translocation, cytochrome c release and apoptosis in primary rat hepatocytes. More importantly, bile acid inhibition of p53-induced apoptosis was associated with decreased p53 DNA-binding activity. Subcellular localization of p53 was also altered by UDCA. Both events appear to be related with increased association between p53 and its direct repressor, Mdm-2, as detected by immunoprecipitation analysis. Posttranscriptional silencing of the mdm-2 gene confirmed its involvement in the antiapoptotic function of UDCA. In conclusion, these results further clarify the antiapoptotic mechanism of UDCA and suggest that modulation of Mdm-2/p53 interaction is a prime target for this bile acid.

HEPATIC STAT3 ATTENUATES SYSTEMIC INFLAMMATORY RESPONSE AND LETALITY IN SEPTIC MICE

Ryotaro Sakamori, Tetsuo Takehara, Hayato Hikita, Akira Sasaki, Keisuke Kohga, Akio Uemura, Shinjiro Yamaguchi, Tomohide Tatsumi, Kazuyoshi Ohkawa, Norio Hayashi

Background: IL-6 is an important modulator of pathophysiological changes in sepsis. STAT3 is a key signaling molecule of the IL-6 response during inflammatory response. However, the significance of hepatic STAT3 in the process of sepsis is unclear. In the present study, we used a murine model of septic shock and compared outcomes between hepatocyte-specific STAT3 KO (L-STAT3) mice and wild-type littermates. Materials and Methods: We generated L-STAT3 mice by the Cre/loxP recombinant system. CLP-induced sepsis was performed using cecal ligation with a single 23-gauge puncture (CLP). STAT3 activation in the liver was evaluated by western-blotting. The concentration of TNF-α, IL-6, IFN-γ and IL-10 in the serum was determined with multi-analyte profiles in sera. Furthermore, we isolated hepatocytes from L-STAT3 KO mice and control mice, collecting the conditional medium of hepatocytes. Next, we cultured murine macrophage cell line RAW264.7 in the culture supernatants of hepatocytes with or without LPS, following the measurement of TNF-α, IL-6, and IL-10. Results: STAT3 was rapidly phosphorylated in the liver of wild-type mice after CLP but was not in that of L-STAT3 mice. The levels of serum acute phase proteins including haptoglobin and fibrinogen increased in wild-type mice 24 hours after CLP but only to lesser extents in L-STAT3 mice. Of interest is the finding that the rate of CLP-induced mortality was significantly higher in L-STAT3 mice than in wild-type mice. The levels of pro-inflammatory cytokines including TNF-α, IL-6 and IFN-γ which are known to be associated with sepsis-induced mortality was significantly higher in L-STAT3 mice than those in wild-type mice. We injected 4 mg/kg of LPS into LSTAT3 and wild-type mice and confirmed that fixed dose of endotoxin also induced hyper-inflammatory responses in LSTAT3 mice. The wild-type hepatocytes produced more haptoglobin than KO hepatocytes, and hepatocyte culture supernatants suppressed the levels of cytokines produced from RAW cells. Suppressive activity of KO hepatocytes supernatant was significantly weaker than that of wild-type hepatocyte supernatant. Conclusion: Liver STAT3 deficiency increased inflammatory cytokine production and mortality in a murine model of septic shock. Hepatic STAT3 represses systemic hyper-inflammatory response by stimulating hepatic production of soluble substance(s) that can attenuate immune cell overactivation and also improves host survival during septic condition.

gp130-dependent pathways. To study this mechanism we combined conditional knockout and knockin technology for gp130 and generated hepatocyte-specific gp130 knockout (hepaΔgp130) mice that are either deficient for hepatocyte-specific gp130-dependent Ras/Erk (hepaΔgp130RAS) or STAT (hepaΔgp130STAT) activation. We thus performed PH in these mice and hepatocyte proliferation, cell cycle regulation, Erk1/2 and STAT3 activation, expression of its negative regulator SOCS3 and the acute phase response was analyzed in all mouse strains. According to the major impact of gp130-dependent signalling on acute phase gene (APG) regulation after PH it was blocked in hepaΔgp130STAT animals, while hepaΔgp130RAS mice showed an enhanced APG response. As the STAT3 regulating feedback loop is blocked in hepαΔgp130RAS mice prolonged STAT3 activation and significantly higher SOCS3 mRNA levels were evident and associated with a later start of hepatocyte proliferation 48 h after PH. More detailed analysis of cell cycle parameters demonstrated that G1-S-phase transition was delayed in these animals. To define the role of SOCS3 during hepatocyte proliferation, primary hepatocytes were co-stimulated with IL-6 and HGF. Higher SOCS3 expression in gp130-ΔRas hepatocytes correlated with delayed hepatocyte proliferation in vivo and in vitro suggesting that the strength of SOCS3 expression is involved in controlling DNA synthesis. Next, we tested the impact of LPS - mimicking bacterial infection - on liver regeneration. LPS and PH induced SOCS3 in all animal strains and delayed cell cycle progression. Additionally, IL-6/gp130-dependent STAT3 activation in hepatocytes was essential in mediating protection and thus required for maximal proliferation. In summary, our results implicate that gp130-dependent STAT signalling during liver regeneration in hepatocytes via SOCS3 controls timing of G1/S-phase transition thereby providing protective signals that are important to allow hepatocyte proliferation during stress conditions.

1225 LIVER TETRAPLOIDIZATION IS TRIGGERED BY WEANING UNDER AN INSULIN SIGNAL

Severine Morizur, Germain Margall-Ducos, Dominique Couton, Chantal Desdouets; Genetic and Development, Institut Cochin - INSERM 567, Paris, France

Hepatocytes polyploidization is an important feature of mammalian liver growth, correlated with ageing and senescence. Whereas hepatocytes of newborn are exclusively diploid, during post-natal growth, the liver parenchyma undergoes progressive polyploidization, with the appearance of tetraploid and octoploid cells classes with one or two nuclei. In adults, liver polyploidization is differently regulated upon loss of liver mass and liver damage. Interestingly, partial hepa-tectomy induces marked cell proliferation, followed by an increase in liver cell ploidy. In contrast, in different liver pathologies, hepa-tocarcinome for example, growth shifts to a non-polyploidizing pattern and expansion of the diploid hepatocytes population has been found to take place. In a previous study using time-lapse videomicroscopy, our group has clearly established the lineage existing between hepatocytes of different ploidy. We have demonstrated that the appearance of binucleated 2x2n and mononucleated 4n hepatocytes is chronologically controlled during development, binucleated hepatocytes being generated by a process of incomplete cytokinesis. We have now deciphered the molecular mechanism regulating this event.

Indeed, mitotic hepatocytes perform karyogenesis without cleavage plane specification (absence of actin cytoskeleton rearrangement associated with unattached microtubules to the equatorial cortex). Consequently, RhoA pathway, orchestrator of cytokinesis, is not activated leading to the genesis of tetraploid cells. Furthermore, we also demonstrated that weaning triggers this process. Indeed, if animals are weaned at 15 days, we clearly observed that the incomplete cytokinesis process is largely initiated at 19 days in contrast with animals that stay with the mother with no access to nutriment. Weaning period is clearly associated with physiological changes, such as modification of nutritional diet, hormonal variations and circadian clock appearance. We are now trying to define which cell signalling pathways trigger incomplete cytokinesis. By modifying the nutrient supply at the weaning period (high/low fat diet), we have demonstrated that glucids are not involved in the induction of binucleation process. Moreover, we are currently assessing the effect of modifying the level of insulin around the time of weaning. Our preliminary results indicate that when insulin signalling is impaired, binucleation process is not initiated. Insulin regulates several pathways involved in distinct cell cycle events and we are now in the process to define which of them could control the genesis of tetraploid progenies.

1226 MOLECULAR MECHANISMS OF ANTI-APOTOTIC AND ANTI-OXIDANT EFFECTS OF GRAPE AND ITS COMPOUNDS

Jing Yu1, Yumin Xu1, Zhongying Bao1, Vladimir Khaoustov1,2, Boris Yoffe1,2; 1Baylor College of Medicine, Houston, TX; 2Michael E. Debaky VAMC, Houston, TX

Background & Aims: Apoptosis plays a critical role in variety of liver diseases such as hepatitis, cirrhosis, and hepatocellular carcinoma. We reported that freeze-dried grape powder (FDGP) attenuates mitochondria-induced apoptosis. However, the underlying mechanisms remained unknown. Aim of this study was to analyze the mechanism responsible for anti-apoptotic effect of FDGP or its active components. Methods & Results: We examined signaling pathways induced by FDGP and its active components such as epicatechin, cyanidin, quercetin and resveratrol in human hepatoma cells, Huh7 using Western blot analysis. After titration, 0.8 mM H2O2 was used to generate the oxidative stress and 400µM taurodeoxycholic acid (TDCA) for mitochondria-induced apoptosis as analyzed by MTT assay. FDGP (300µg/ml) dramatically decreases TDCA-induced activation of caspase-3, caspase-7, caspase-9 and Bax and restores levels of PCNA, p53 and NF-kB. The reduction of TDCA-induced apoptosis with FDGP treatment was confirmed by flow cytometry. Interestingly, both epicatechin (50-150µM) and cyanidin (30-100µM) reduced TDCA-induced apoptosis in a dose-dependent manner. No effects were seen with resveratrol and quercetin at the similar concentrations present in FDGP. No anti-apoptotic effects were seen even with higher doses although resveratrol increased expression of Sir1, an important modulator of apoptosis/cell survival and lifespan expansion. H2O2-induced stress resulted in downregulation of Akt and PCNA expression levels and induced phosphorylation of c-Jun in a dose- and time-dependent manner. Pretreatment with FDGP restored the level of Akt and PCNA expression and inhibited c-Jun phosphorylation. Similarly, both epicatechin and cyanidin reduced H2O2-induced apoptosis whereas no effects were seen with quercetin or resveratrol. Conclusion: FDGP...
reduces the oxidative stress and mitochondria-induced apoptosis. The mechanisms of anti-apoptotic effects of FDGP were associated with prevention of mitochondrial damage, inhibition of c-Jun/AP-1, and upregulation of Akt expression. We speculate that epicatechin and cyanidin are the active compounds of FDGP involved in attenuation of mitochondria- and H2O2-induced apoptosis. No effects were seen resveratrol and quercetin, although high concentrations of resveratrol induced Sirt1 expression. These findings may contribute to our understanding of the molecular mechanisms of anti-apoptotic and anti-oxidant effects of grape and its components and assist in developing clinical protocols to treat a variety of stress-mediated liver conditions.

1227 EXPRESSION AND LOCALIZATION OF ATYPICAL PKC ISOFORMS IN LIVER PARENCHYMAL CELLS
Claudia Stross, Verena Keitel, Ralf Kubitz, Dieter Häussinger; Klinik für Gastroenterologie, Hepatologie und Infektiologie, Heinrich Heine Universität Düsseldorf, Düsseldorf, Germany

Members of the protein kinase C (PKC) family transduce extracellular stimuli to the cellular signalling networks. The family comprises 10 isoforms that can be subdivided into three classes: the classical PKCs (α, β, γ and δ), the novel PKCs (ε, η and θ) and the atypical PKCs (ζ and η/ζ), which share 72% amino acid (aa) identity. Expression of PKCs and localization of atypical PKCs in hepatocytes is only partially characterized. Methods: Full-length PKCζeta and iota were cloned from total RNA of human liver and fused to a yellow fluorescent protein (YFP-tag). PKCζeta-YFP and PKCiota-YFP were overexpressed in HEK293 cells in order to test the specificity of commercially available aPKC antibodies by immunofluorescence and Western blot analysis. Subcellular localization was analyzed by differential centrifugation with separation of cytosol, basolateral and canalicular membranes and by immunofluorescence in isolated rat hepatocytes and liver sections. Results: Expression of PKCζeta, βζ, δζ, εζ and ηζ in isolated hepatocytes was confirmed by western blot analysis. Additionally, PKCζeta-mRNA and protein were detected in hepatocytes. A PKCζeta antibody directed against the 20 aa from the N-terminus was specific for PKCζeta in Western blot. Two PKC iota antibodies (immunogens: aa 168-243 and 404-587) were specific for PKCiota and did not react with PKCζeta. The antibody H-1 (immunogen: aa 542-592 from PKCζeta) detected PKCζeta as well as PKCiota. Using the specific antibodies a strong canalicular staining of PKCζeta in immunofluorescence studies of hepatocytes and liver sections was found. Analyzing the subcellular localization by cell fractionation and Western blotting, PKCζeta was faintly detectable in the cytoplasmic fraction, and showed a strong signal in the basolateral and canalicular membrane fractions. PKCζeta was exclusively localized in the canalicular fraction. Discussion/Conclusion: This study demonstrates the expression of PKCiota in hepatocytes. Both atypical PKC isoforms exhibit a prominent canalicular localization in liver parenchymal cells proposing a role in the regulation of canalicular transporters. The exact topology of atypical PKCs needs to be considered in the functional evaluation PKCζeta and PKCiota in hepatocytes.

1228 ESTROGEN RECEPTORS ACTIVATE THE EXPRESSION OF THE HUMAN ENTEROHEPATIC TRANSPORTER GENES SLC10A2 AND SLCO1B1 BY ENHANCING THE DNA-BINDING OF HNF-1α
Jyrki J. Eloranta, Christian Hiller, Gerd A. Kullak-Ublick; Division of Clinical Pharmacology and Toxicology, University Hospital Zurich, Zurich, Switzerland

Background: Estrogens are steroid hormones that elicit complex transcriptional programmes in many metabolic pathways. Most actions by estrogens take place through their functions as ligands for the estrogen receptor-α (ERα) and -β (ERβ), which bind to the response elements in the regulatory regions of their target genes. Additionally, ERs possess nongenomic functions, independent of their DNA-binding. Estrogenic effects on enterohepatic transporter gene expression have been widely studied in rodents, but little is known about regulation of transporter genes by estrogens in the human liver and intestine. Aim: To investigate the mechanism of regulation of the human transporter genes SLC10A2 (encoding the apical intestinal sodium-dependent bile acid transporter ASBT) and SLCO1B1 (encoding the hepatic organic anion transporting polypeptide OATP1B1) by ERs and estrogens. Methods: Regulatory regions of the human SLC10A2 and SLCO1B1 genes were cloned, linked to the luciferase reporter gene and analyzed in transient transfections in human intestine- and liver-derived cell lines. In vitro and in vivo protein binding to DNA were studied in EMSAs and ChIP assays, respectively. Results: Exogenous expression of ERα and ERβ increased the promoter activities of the human SLC10A2 and SLCO1B1 genes. Treatment of cells with 17β-estradiol enhanced ER-mediated activation of the two genes. No ER binding sites could be identified within either promoter. Promoter mutagenesis showed that in the context of both transporter genes the ER response was mediated through the binding sites for hepatocyte nuclear factor-1α (HNF-1α). The ER-responsive HNF-1α binding sites are located in the 5′-UTR of the human SLC10A2 gene (+305/+317) and in the proximal region of the human SLCO1B1 promoter (51′-39). In EMSA and ChIP assays, DNA-binding of HNF-1α and recruitment of HNF-1α to the transporter promoters were increased by ERs and 17β-estradiol. ERs did not increase HNF-1α mRNA or protein levels or HNF-1α promoter activity, but enhanced the interaction between the HNF-1α protein and its DNA response elements by post-translational mechanisms. Conclusions: We have revealed a novel signalling cascade, by which ERs and estrogens activate the expression of the human enterohepatic transporter genes SLC10A2 and SLCO1B1 via HNF-1α response elements in their promoter regions. ERs do not affect HNF-1α expression levels, but mediate enhanced association of HNF-1α with its target genes. By this mechanism, elevated estrogen levels may increase bile acid uptake into human enteroocytes by ASBT and enhance extraction of organic anions and drugs from portal blood into human hepatocytes by OATP1B1.

1229 S6K1 INHIBITION BY A NOVEL CLASS OF DITHIOLETHIONES ABROGATES INSULIN RESISTANCE INDUCED BY HYPEROSMOTIC STRESS
Eun Ju Bae, Yoon Mi Yang, Sang Geon Kim; College of Pharmacy, Seoul National Univ., Seoul, South Korea

The development of insulin resistance in the clinical situations associated with hyperosmotic dehydration is suggested to
 impair the metabolic insulin effects in liver and peripheral tissues. Inhibition of insulin resistance recovers the ability of insulin to suppress hepatic glucose production, and to promote glucose uptake in peripheral tissues, therefore, pharmaceutical interventions to prevent insulin resistance are of therapeutic interest. Oltipraz, a prototype diithiolethione, inhibits TGF-β1 and has the ability to regenerate cirrhotic liver, which provided a basis for its clinical trial. We previously found that novel synthetic diithiolethiones including oltipraz prevent TNFα-induced hepatic insulin resistance via AMP-Activated protein kinase (AMPK)-dependent p70S6 kinase (S6K1) inhibition. Although hyperosmotic stress blocks insulin-dependent PI3K-Akt signal by mTOR pathway, in a certain cellular context, it improves glucose homeostasis via AMPK activation. This study investigates whether synthetic diithiolethiones affect hyperosmolarity-induced insulin resistance and altered cell signaling. In HepG2 cells, oltipraz decreased hyperosmolar sorbitol-induced AMPK activation although oltipraz alone also activated AMPK. The reduced intracellular ATP level by sorbitol, which could be responsible for its AMPK activation, was completely restored to control level by oltipraz pretreatment. Moreover, oltipraz abolished sorbitol-induced S6K1 phosphorylation. Oltipraz inhibited the ability of sorbitol to induce insulin receptor substrate (IRS)1 serine phosphorylation at Ser312. An experiment using dominant negative S6K1 supports the essential role of S6K1 in the hyperosmolarity-stimulated phosphorylation of IRS1. Oltipraz treatment recovered insulin signal impaired by hyperosmotic stress, whereas constitutively active S6K1 transfection eliminated the protective effects of oltipraz on IRS1 and glycogen synthase kinase (GSK)3β phosphorylations, indicating that oltipraz protects insulin responses by inhibiting S6K1 activation. Protection of insulin signal by oltipraz from hyperosmotic stress promoted glucose uptake in C2C12 myotubes, but not in 3T3-L1 adipocytes. Synthetic diithiolethiones comparably inhibited S6K1 activity and insulin resistance. Among the diithiolethiones examined, 4,5,6,7-tetrahydrobenzo-1,2-dithiole-3-thione and 5-(6-hydroxy-3,4-dimethyl-2-thioxo-1,3-dihydro-1H-imidazol-2-yl)thiophene enhanced insulin-dependent glucose uptake in C2C12 myotubes against hyperosmotic stress. The results of this study demonstrate that diithiolethiones prevent insulin resistance induced by hyperosmolarity, and thereby improve insulin responses, which result from S6K1 inhibition.

1230 ADAM17 PROMOTES ERK-MEDIATED PHOSPHORYLATION OF SER112 IN BAD
Katsuhiro Senda, Haruhisa Nakao, Shunsuke nojiri, Takashi Joh, Tomokatsu Miyaki; Department of Gastroenterology and Metabolism, Nagoya City University, Nagoya, Japan

Background: ADAM17, which belongs to the ADAMs family of transmembrane protein, participates in cytokine and growth factor shedding and cell proliferation. Although ADAM17 has been implicated in disease pathologies and development of cancer, a few studies have been reported about liver cancer. ADAM17 also mediates shedding of both cytokines and cytokine receptors and plays important roles in cell signaling. Recently, an association between ADAM17 and ERK has been reported. However, the influence of ADAM17 on the downstream signaling of ERK has not been confirmed. Aims: 1. To examine whether ADAM17 is expressed in liver cancer cell lines. 2. To determine whether ADAM17 in liver cancer cell lines could regulate the activation of BAD which is located downstream in ERK signaling pathways and plays an important role in apoptosis. Materials and Methods: Expression of ADAM17 was confirmed in human liver cancer cell lines (HuH7, PLC/PRF/5, SKHep) by western blot analysis. Human liver cancer cells were transfected with either small-interfering RNA (siRNA) targeting ADAM17 to inhibit ADAM17 expression or control siRNA using lipofectamine. Phosphorylation of ERK, AKT, and BAD under ADAM17 expressed or unexpressed condition were analyzed by western blot. U0126 was used to inhibit Erk/MEK activation. Results: ADAM17 was expressed in HuH7, PLC/PRF/5, SKHep cells and the expression was inhibited by ADAM17 specific siRNAs in all cell lines. Although phosphorylation of ERK was enhanced in liver cancer cells with time after EGF stimulation, siRNA to ADAM17 inhibited ERK phosphorylation by EGF stimulation. We examined whether ADAM17 could affect AKT phosphorylation because BAD can be activated by both ERK and AKT pathways. However, the activation of AKT was unrelated to the presence of ADAM17 expression. The phosphorylation of BAD at Ser155 was not observed and the phosphorylation at Ser136 showed very weakly. ADAM17 didn’t have an effect on the phosphorylation at both Ser136 and Ser155. On the other hand, the phosphorylation of BAD at Ser112 was boosted by EGF stimulation and was inhibited by siRNA targeting ADAM17. Moreover, the phosphorylation of BAD at Ser112 disappeared with U0126, MEK/ERK inhibitor. Conclusion: We confirmed the expression of ADAM17 in human liver cancer cell lines. ADAM17 enhanced the activation of ERK and the phosphorylation of BAD at Ser112 by EGF stimulation in human hepatocellular carcinoma cells.

1231 OVEREXPRESSION OF THE LIVER TRANSCRIPTION FACTOR HNF6 ACCELERATES HEPATOCYTE PROLIFERATION DURING MOUSE LIVER REGENERATION
Yuichi Yoshida1, Yongjun Tan2, Douglas E. Hughes3, Shinji Tamura1, Norio Hayashi1; 1Department of Gastroenterology and Hepatology, Osaka University, Suita, Osaka, Japan; 2The Biomedical Engineering Center, Hunan University, Yuelu District, China; 3Departments of Biochemistry and Molecular Genetics, University of Illinois at Chicago, College of Medicine, Chicago, IL

Background and Aims: Hepatocyte nuclear factor 6 (Hnf6, also known as Oc1) belongs to ONECUT transcription factor family whose members play essential roles in development, cellular differentiation, and metabolism. Mouse genetic analysis of Hnf6 null embryos demonstrated that Hnf6 is essential for development of the pancreas, gall bladder and both intrahepatic and extrahepatic bile ducts. Published promoter microarrays combined with chromatin immunoprecipitation (ChIP) from hepatoma cells shows that Hnf6 binds to several endogenous promoters involved in proliferation such as Cdc25A, E2F and Cdk2, suggesting that Hnf6 might be involved in hepatocyte proliferation during liver regeneration. To test our hypothesis, we investigated whether overexpression of Hnf6 affects stimulate hepatocyte proliferation following mouse partial hepatectomy. Methods: CD-1 mice infected with replication defective adenovirus expressing either the mouse Hnf6 cDNA (AdHnf6) or the control bacterial LacZ (β-Galactosidase; AdLacZ) gene were subjected to partial hepatectomy (PHx). The regenerating livers were harvested at several time points between 32hr and 48hr after PHx. Hepatic DNA synthesis was
assessed by immunohistochemical staining of bromodeoxyuridine (BrdU) incorporation. Furthermore, cotransfection and ChIP assays were used to determine transcriptional target promoters of HNF6 and its target genes. Results: Overexpression of HNF6 during mouse liver regeneration caused a significant increase in the number of hepatocytes entering DNA replication. This accelerated proliferation in AdHNF6 infected mouse livers was associated with increased expression of the hepatocyte mitogen Transforming Growth Factor α (TGFα), the cell cycle regulators Cyclin D1, Cdk2 and Forkhead Box m1 (Foxm1) transcription factor. Cotransfection and ChIP assays demonstrated that TGFα, Cyclin D1 and HNF6 promoters were direct transcriptional targets of HNF6 and that combining HNF6 and Foxm1 further enhanced transcriptional activities of the TGFα promoter. We also showed that HNF6 associated with Foxm1 protein in the regenerating livers and this complex formation resulted in activation of Foxm1 transcription. Furthermore, cotransfection and ChIP assays demonstrated that both Foxm1 and HNF6 proteins activated transcription of the endogenous HNF6 promoter region. Conclusion: Our current studies demonstrate that the liver-enriched HNF6 transcription factor could contribute to liver regeneration through transcriptional activation of cell cycle regulatory genes.

THE HUMAN SMALL HETERO DIMER PARTNER (SHP) PROMOTER CONTAINS INDEPENDENT AND UNCONVENTIONAL 9-CIS RETINOIC ACID- AND BILE SALT-RESPONSIVE ELEMENTS

Martijn O. Hoeke, Janette Heegsma, Klaas Nico Faber; Department of Gastroenterology and Hepatology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands

The small heterodimer partner (SHP) is an important transcriptional regulator of bile salt homeostasis. It represses expression of key genes in liver and intestine involved in bile salt biosynthesis and transmembrane bile salt transport. SHP itself is positively regulated by the Farnesoid X Receptor (FXR), the mammalian bile salt sensor. FXR functions as a heterodimer with the Retinoid X Receptor α (RXRα). FXR is activated by the bile salt chenodeoxycholic acid (CDCA) and RXRα by the vitamin A derivative 9-cis retinoic acid (9cRA). Previously, a FXR-responsive element (FXRE) has been identified at position -291/-279 in the hSHP promoter (Goodwin et al., 2000). Recently, we found that 9cRA differentially affects CDCA-induced expression of FXR target genes. 9cRA stimulates and fully represses CDCA-induced expression of SHP and the bile salt export pump (BSEP), respectively. In vitro binding studies revealed that 9cRA inhibits binding of FXR/RXRα to the FXRE. Here, we studied the molecular mechanism of the co-stimulatory effect of CDCA and 9cRA on SHP expression in a human intestinal cell line. The human colon carcinoma cell line DLD-1 was transiently transfected with hFXR- and hRXRα-expression plasmids and cultured in the presence or absence of CDCA and/or 9cRA. Deletion mutants of a 579-bp human SHP promoter element in a luciferase reporter plasmid were generated to determine the location of CDCA and/or 9cRA responsive elements. Transcription of FXR target genes was quantified by Q-PCR and the promoter activity of hSHP was determined by luciferase reporter assays. CDCA and 9cRA induce transcription of hSHP in DLD-1 cells 39- and 12-fold, respectively. Maximal SHP expression (98-fold) was observed when DLD-1 cells are co-exposed to both ligands. Similar regulation was observed for the -569/+10 hSHP promoter element. SHP promoter fragments that were 5' truncated up to position -122 still showed CDCA-induced luciferase expression. This DNA fragment does not contain a sequence similar to the previously identified FXREs. 9cRA dependent activation was lost when truncating the hSHP promoter to -278. Induction of transcription by CDCA and 9cRA were dependent of FXR and RXRα. The hSHP promoter contains a novel bile salt-responsive element, which is different from the previously suggested FXRE at position -291/-279. The hSHP promoter contains a separate RXRα/9cRA response element at position -303/-279. Independent regulation of hSHP by bile salts and 9cRA may be important to maintain adequate levels of bile salt synthesis and transport during cholestatic conditions that are associated with reduced vitamin A levels.

ROLE OF FARNESOID X RECEPTOR IN REGULATING HEPATIC LIPID HOMEOSTASIS

Bo Kong, Noriko Esterly, Manimaran Rengasamy, Grace Guo; Department of Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS

Nuclear receptor farnesoid X receptor (FXR) plays an important role in cholesterol metabolism and bile-acid homeostasis. A number of studies have shown that FXR is critical in the regulation of fatty acid metabolism and triglyceride homeostasis. But the mechanism by which and to what extent FXR regulates the lipid metabolism remains to be elucidated. In order to clarify the roles of FXR in liver lipid metabolism, new mouse models were developed with hepatocyte-specific or enterocyte-specific deletion of the FXR gene (AFXR, FXR albumin Cre (+/-) mice; and VFXR, FXR villin Cre (+/-) mice). Comparing these with the whole-body FXR knockout mice (FXR KO), the serum lipid profiles of FXR KO, AFXR and VFXR Cre (+) or Cre (-) mice were determined after fed either a chow diet or high-fat diet for 4 weeks. The hepatic lipid content was determined by oil-red O staining. Northern blot was employed to measure the expression of hepatic and intestinal genes involved in fatty acid uptake, intracellular transport, lipogenesis and lipoprotein assembly, in mice on the chow diet or high-fat diet for 7 days. Our data showed that the expression of FXR in both the liver and intestine is important in regulating triglyceride and fatty acid homeostasis; in addition, using the tissue-specific FXR knockout mice, our results suggest that the expression of FXR in extra enterohepatic sites is also involved in lipid regulation. These data provide a basis for further understanding of FXR function in lipid metabolism.

HOMOCYSTEINE-INDUCED INHIBITORY EFFECTS ON ADIPONECTIN PRODUCTION IN ALCOHOLIC LIVER DISEASE

Zhenyuan Song1, Zhanxiang Zhou1, Ian V. Deaciuc1, Theresa S. Chen1, Craig J. McClain1,2; 1Medicine/Gastroenterology, University of Louisville, Louisville, KY; 2Louisville VAMC, Louisville, KY

Although recent evidence suggests that the down-regulation of the adipocyte hormone adiponectin has pathophysiological importance in the development of alcoholic liver
disease (ALD), the underlying mechanisms are still elusive. Abnormal hepatic methionine metabolism and hyperhomocysteinemia induced by prolonged alcohol exposure has been reported both in clinical and experimental studies of ALD. Here, we conducted both in vivo and in vitro experiments to examine the effects of prolonged alcohol exposure on homocysteine levels in adipose tissue and its potential involvement in regulating adiponectin production in ALD. C57BL/6 male mice fed a Lieber-DeCarli ethanol-containing liquid diet were utilized as the animal model of ALD. Our results demonstrated that chronic alcohol exposure decreased the circulating adiponectin concentration and adiponectin mRNA and protein levels in epididymal fat pads. Alcohol feeding induced modest hyperhomocysteinemia and increased homocysteine levels in the epididymal fat pad, which was associated with decreased mRNA levels of cystathionine-β-synthase (CBS). Betaine supplementation (1.5%, m/v) in the alcohol fed mice reduced homocysteine accumulation in the adipose tissue, and was accompanied by improved adiponectin levels. Moreover, in our in vitro study, we found that exogenous homocysteine administration reduced gene expression, protein production, and secretion of adiponectin in primary adipocytes. Furthermore, CBS/- mice had lower circulating adiponectin levels. Mechanistic studies revealed that both inactivation of the extra-cellular signal regulated kinase 1/2 (ERK1/2) pathway and induction of the endoplasmic reticulum (ER) stress response, specifically CHOP expression, may contribute to the inhibitory impact exerted by homocysteine. In conclusion, chronic alcohol feeding caused abnormal accumulation of homocysteine in adipocytes, which contributes to decreased adiponectin production in ALD. Our findings provide a novel mechanism by which betaine supplementation may have therapeutic efficacy in ALD.

2135 PROTEIN KINASE C REGULATES H2O2-INDUCED HEPATOCYTES NECROSIS BY SUPPRESSION OF PROTECTIVE SIGNALING VIA AMP ACTIVATED KINASE AND AKT

Saberi Behnam1, Mie Shinohara1, Naoko Hanawa1, William A. Gaarde2, Derick Han1, Neil Kaplowitz1; 1GI/Liver, USC, Los Angeles, CA; 2Isis Pharmaceuticals, San Diego, CA

Reactive oxygen species such as H2O2 have been suggested to mediate liver damage during inflammation, and drug- and alcohol-induced liver injury. Cell death induced by H2O2 has been traditionally attributed to oxidation and damage of cellular macromolecules (e.g. proteins, DNA, lipids) by H2O2. However now it is known that reactive oxygen species can affect many signal transduction pathways including Protein kinase C (PKC; family of serine/threonine kinases) to modulate cell death. Treatment of primary cultured hepatocytes with PKC inhibitors (Ro-31-8425 or Bisindolylmaleimide I) significantly decreased necrosis caused by H2O2 (80% decrease at 300 μM H2O2). Ro-31-8425 and Bisindolylmaleimide I, caused translocation of PKCα and PKCε to the membrane in an inactive form. Knocking down PKCα and/or PKCε with antisense in hepatocytes did not protect against necrosis induced by H2O2 suggesting that these two isoforms of PKC are not the only isoforms that explain protective effect of PKC inhibitors. PKC inhibitor treatment was also found to activate Akt (Protein kinase B), an anti-apoptotic serine/threonine kinase important in insulin signaling, and AMPK (AMP-activated protein kinase), an important regulator of metabolism in cells. PKC inhibitor treatment increased levels of phospho-Akt (serine 473), which were reduced following H2O2 treatment in hepatocytes. Akt inhibitors partially inhibited the protective effect of PKC inhibitor, suggesting that the protective effects of PKC inhibitor was partially mediated through Akt activation. PKC inhibitor treatment was also found to increase AMPK phosphorylation (threonine172) in hepatocytes. Compound C, a selective AMPK inhibitor, significantly reduced the protective effect of PKC inhibitors against necrosis induced by H2O2. Similarly, AICAR and metformin, AMPK activators that increase energy generation in cells, significantly inhibited H2O2-induced necrosis (45% decrease at 300 μM H2O2). These results suggest that activation of AMPK, possibly through activation of energy generating pathways, plays a protective role against H2O2-induced necrosis in hepatocytes. Taken together, our data suggests that PKC regulates Akt and AMPK signaling pathways linked to energy and metabolism, to modulate H2O2-induced necrosis in hepatocytes. H2O2 activates PKC which suppresses activation of AMP kinase and Akt and consequently inhibition of PKC unmasked signaling pathways which lead to resistance to necrosis.

1236 ALTERING TRANSPLANTED CELL ENGRAFTMENT AND PROLIFERATION IN THE LIVER THROUGH PARACRINE SIGNALING WITH COTRANSPLANTATION OF LIVER SINUSOIDAL ENDOTHELIAL CELLS (LSEC) AND HEPATOCYTES IN MICE

Antonia Follenzi1,2, Ekaterine Berishvili1, Brigaid Joseph1, Simone Merlin2,1, Sanjeev Gupta1; 1GI/Liver, USC, Los Angeles, CA; 2Isis Pharmaceuticals, San Diego, CA

After cell transplantation in liver, multiple cell compartments, including endothelial, stellate and Kupffer cells are activated and cell-cell interactions regulate transplanted cell engraftment and proliferation. To develop strategies for liver-directed cell and gene therapy, insights into such cell-cell interactions will be helpful, particularly for improving transplanted cell engraftment, survival and proliferation. Recently, we demonstrated that under suitable circumstances transplanted LSEC can engraft, function and reconstitute significant portions of the hepatic endothelium. Similarly, transplanted hepatocytes can repopulate the liver and replace deficient functions. To establish potential roles of LSEC in engraftment of transplanted hepatocytes, we optimized protocols in mice preconditioned with the pyrrolizidine alkaloid, monocrotaline (MCT), which causes significant endothelial injury and improves transplanted cell engraftment. We used transgenic GFP mice as LSEC donors and wild-type C57Bl/6 mice as hepatocyte donors. To deposit cells in hepatic sinusoids, we transplanted LSEC intraportally and hepatocytes intrasplenicly in syngeneic DPPIV- mice, followed by cell engraftment analysis after 7 d. GFP-positive transplanted LSEC were integrated in the sinusoidal lining and DPPIV-positive transplanted hepatocytes were in liver parenchyma. Comparison of recipients where only LSEC, only hepatocytes, or both LSEC and hepatocytes were transplanted, showed that cell cotransplantation improved hepatocyte engraftment. Next, to establish whether genetic manipulation of LSEC will offer further opportunities for cotransplantation studies, we used lentiviral vectors (LV) to transduce primary LSEC and hepatocytes. We built a bidirectional LV construct to express hHGF and GFP and a
bicistronic LV construct to express hVEGF and GFP. Transgene expression was verified in primary mouse LSEC and hepatocytes in vitro. When LV-modified cells were transplanted into MCT-conditioned mice, LSEC engrafted and proliferated, similar to control LSEC from GFP transgenic mice throughout the 1 month study duration. Conclusions: Cotransplantation of primary LSEC improved engraftment of transplanted hepatocytes. As LV-transduced LSEC survived, proliferated and expressed introduced transgenes over the long-term, this offers paradigms to establish the effects of multispecific paracrine factors, i.e., hHGF and VEGF, on transplanted cell engraftment, proliferation and function. The ability to reconstitute the liver with genetically-modified LSEC and/or hepatocytes will offer potent ways to investigate biological mechanisms and to pursue cell and gene therapy in suitable disorders.

1237 USEFULNESS OF ONCOSTATIN M GENE THERAPY ON LIVER DAMAGE INDUCED BY DIMETHYLNITROSAMINE IN RATS
Tetsuhiro Hamada1,2, Ayuko Sato2, Ikuko Torii2, Jiro Fujimoto3, Tohru Tsujimura2; 1Surgery, Hyogo college of medicine, Nishinomiya, Japan; 2Pathology, Hyogo college of medicine, Nishinomiya, Japan

The liver has a remarkable ability to respond to injuries inflicted by various causes, such as partial hepatectomy, toxic exposure, and virus infection. Hepatocytes, that are liver parenchymal cells and normally in the quiescent G0 phase, reenter the cell cycle following injury to restore its mass, architecture, and function. In this process, a number of growth factors and cytokines have been reported to be involved. Oncostatin M (OSM) is a member of the interleukin (IL)-6 cytokine family that includes IL-6, IL-11, leukemia inhibitory factor, ciliary neurotrophic factor, cardiotrophin-1, and novel neurotrophin-1/B-cell-stimulating factor-3. Because it has been recently reported that liver regeneration is impaired in OSM-specific receptor deficiency (-/-) mice and CCl4-induced acute liver failure is ameliorated by the administration of OSM in mice, it is likely that OSM plays a crucial role in liver regeneration. To assess the usefulness of OSM gene therapy in liver regeneration, we here examined whether the introduction of rat OSM cDNA enhances the regeneration of livers damaged by dimethylnitrosamine (DMN) in rats. Repeated injection of rat OSM cDNA in hemagglutinating virus of Japan envelope into the spleen resulted in the exclusive expression of OSM protein in Kupffer cells of the livers, which accompanied by the increase of body weight, liver weight, and serum albumin levels and the reduction of serum liver injury parameters, such as bilirubin, aspartate aminotransferase, and alanine aminotransferase, and a serum fibrosis parameter, hyaluronic acid. Histological examination showed that OSM gene therapy reduced centrilobular necrosis and infiltration of inflammatory cells and augmented hepatocyte proliferation. The apoptosis of hepatocytes identified by TUNEL staining and the fibrosis identified by Azan stain were also suppressed by OSM gene therapy. In addition, time-course studies on OSM gene therapy prior to or after DMN treatment showed that this therapy was effective not only in enhancing regeneration of hepatocytes damaged by DMN but also in preventing hepatic cytotoxicity caused by subsequent treatment with DMN. These results indicate that OSM is a key mediator for proliferation and antianapoptosis of hepatocytes in liver regeneration and suggest that OSM gene therapy is useful, as preventive and curative means, for the treatment of patients with liver damage.

1238 SEROTONIN 2B RECEPTOR SIGNALING: A NOVEL NEGATIVE REGULATOR OF LIVER GROWTH
Mohammad R Ebrahimkhani1, Luc Maroteaux2, Fiona Oakley1, Derek A Mann3; 1Liver Research Group, Institute of Cellular Medicine, School of Clinical Medical Sciences, University of Newcastle upon Tyne, Newcastle upon Tyne, United Kingdom; 3Developmental of Neurobiology INSERM U616, Hôpital Pitié-Salpêtrière, Paris, France

Background/Aim: Tight regulation of liver cell proliferation is a key event to control organ size during development and hepatic regeneration. Platelet-derived serotonin (5-HT) has recently been described as a stimulator of liver regeneration. A role for 5-HT receptors as regulators of 5-HT-stimulated regeneration has been suggested but is not yet well defined. There are seven distinct classes of 5-HT receptor (5-HT1R to 5-HT7R) and within each class there are multiple subclass members (e.g. 5-HT2A, 5-HT2B and 5-HT2C). The aim of this study was to understand how 5-HT2B receptors contribute to serotonin dependant liver regeneration. Methods: A two-thirds partial hepatectomy or sham laparotomy was performed in wild-type or 5HT2B receptor knockout mice and livers were harvested at 2, 4, 36, 48 and 72 hours post-operatively. Cell proliferation was assessed by staining for Ki67 and BrdU incorporation. Expression of 5-HT2B, 5-HT2A, IL-6, TNF-α, HGF, TGF-α, TGF-β, cyclin E, p21 (Waf1/Cip1) were quantified at the messenger RNA. Results: Gene expressions of hepatic 5-HT2 receptors increase following partial hepatectomy. Maximal liver regeneration in control wild type mice peaked at 36-48 hours post-operatively. Conversely 5-HT2B receptor knockout mice demonstrated increased numbers of proliferating liver cells and prolonged regenerative period compared to wild type mice. Cytokine priming by IL-6 and TNF-α gene expression was reduced in knockout mice. No significant difference in growth factors was observed, however, the anti-proliferative cytokine TGF-β gene was significantly lower in knockout mice at 36-48 hours post-operatively. Additionally P21, a potent inhibitor of cell cycle, was increased in wild type mice 36-72 hours post partial hepatectomy, but interestingly, this increase was not observed in the knockout mice. Conclusion: In conclusion 5-HT2B receptors are negative regulators of hepatic growth and function. We suggest that 5-HT2B functions as a “brake” on hepatocyte proliferation and limits the regenerative capacity of the liver, possibly via a P21-dependent mechanism. These data highlight the potential to exploit serotonin signaling to treat liver disease; 5-HT2B receptors antagonists may enable liver regeneration in end stage liver disease, whilst, agonists will limit the proliferative potential of hepatocytes in hepatocellular cancer.

The sodium-coupled neutral amino acid transporter (SNAT) 4 is expressed in developing mouse liver and regulated by hepatocyte nuclear factor (HNF) 4α.

Hiroki Kondou1, Masayo Yamagata1,2, Kanako Tachikawa1, Toshimi Michigami1; 1Department of Bone and Mineral Research, Research Institute, Osaka Medical Center for Maternal and Child Health, Osaka, Japan; 2Laboratory of Clinical Pharmacology, Osaka Ohtani University, Osaka, Japan

Hepatocyte nuclear factor (Hnf) 4α plays a pivotal role in liver organogenesis. However, the underlying molecular mechanisms by which Hnf4α regulates the fetal liver development remain to be elucidated. In the current study, we have established the organ culture system of mouse fetal liver, and overexpression of Hnf4α was achieved using the adenoviral gene expression system. By applying suppression subtractive hybridization (SSH) to this system, we identified the genes regulated by Hnf4α. Among the identified genes to be up-regulated by Hnf4α over-expression, solute carrier family 38, member 4 (Slc38a4) was included. This gene encodes the sodium-coupled neutral amino acid transporter (SNAT) 4, which is a member of system A amino acid transporters. The expression of SNAT4 in liver organogenesis is unclear. We examined the expression pattern of SNAT4 during liver development, and verified the regulation of its gene expression by Hnf4α. Real-time PCR analyses showed that SNAT4 mRNA was increased in parallel with increase of endogenous Hnf4α mRNA, and SNAT4 mRNA level was predominant among system A amino acid transporters. Whole-mount in situ hybridization revealed that SNAT4 mRNA was expressed in liver bud at E9.5. In situ hybridization using tissue sections from E12.5 adult mice demonstrated that both hepatoblasts and mature hepatocytes expressed SNAT4. Western blot analyses confirmed that SNAT4 protein was detected in fetal liver after E16.5, and also in adult liver. Next, to examine whether Hnf4α regulates SNAT4 expression at transcriptional level, we performed a series of promoter analyses. The 3.7-kbp promoter fragment of the mouse SNAT4 gene was obtained by PCR, and various length of fragments (-3676, -959, -554, -153, -108, and -28/+104 bp from the transcription start site) were inserted into the luciferase reporter vector pGV2 containing neither promoter nor enhancer. Those promoter analyses showed that -153/+104 bp region exhibited maximal responses in HepG2 cells (Hnf4α expressing cells). Furthermore, the transactivation of this promoter was up-regulated by Hnf4α in Hela cells (Hnf4α is not expressed). In conclusion, taking advantage of fetal liver organ culture system and SSH, we identified the SNAT4 as a downstream target of Hnf4α. The expression of SNAT4 increased during the embryonic liver development both in mRNA and protein levels. These results suggest that the development of amino acid transport system is a critical event during liver morphogenesis.

DIFFERENTIAL FUNCTIONS OF CYCLIN E1 AND E2 FOR CELL CYCLE CONTROL AND ENDOREPLICATION DURING LIVER REGENERATION IN MICE

Yulia Nevzorova1, Darjus F. Tscharharganeh1, Peter Scinski2, Christian Trautwein3, Christian Liedtke1; 1Department of Medicine III, University Hospital Aachen, Aachen, Germany; 2Dana-Farber Cancer Institute, Boston, MA

Background and aims: Recent data indicated that cyclin E1 and E2 are dispensable for continuously dividing cells, but are essential for both endoreplication and cell cycle re-entry of quiescent cells. The aim of this study was to explore the role of E-type cyclins during liver regeneration. Methods: 70% partial hepatectomy (PH) was performed in cyclin E1 and E2 knockout mice (KO) and wildtype (WT) controls. Liver regeneration was monitored by measuring the liver/body weight ratio after PH and cell cycle markers for G1/S-Phase (PCNA, cyclin E1, E2), S-phase (Brdu, cyclin A) and M-phase (histone H3, cyclin B). DNA content of hepatocytes was determined by FACS analysis. Activity of cyclinE/cdk2 complexes were analysed through histone H1 kinase assays. Results: Both E1 and E2KO mice performed liver regeneration after PH, but displayed different proliferation kinetics compared to WT controls. E1KO mice revealed a slight delay of G1/S phase transition but stronger hepatocyte proliferation at later time points (48-72h post PH) and a prolonged cdk2 kinase activity compared to WT animals. In E2KO mice we found a contrary effect. Hepatocyte proliferation started earlier and was significantly higher in course of regeneration. Cdk2 kinase activity was observed from 36 to 96 hours post PH whereas in WT mice cdk2 kinase activity was only found from 40 to 48 hours after PH. Accordingly, E2KO mice showed a 40% higher liver/body weight ratio in comparison to control animals 7 days after PH. In E1KO mice the cyclin E2 expression started significantly later after PH with an overall lower expression level compared to WT animals. In contrast, cyclin E1 expression in E2KO was higher than in the control group. Surprisingly, we found only minor differences in M-phase between E1KO, E2KO and control animals. Therefore the ploidy of hepatocytes post PH was analysed by FACS. In E1KO mice we observed a prevalence of diploid cells and only a low number of cells with higher polyploidy index. In contrast, E2KO mice showed much higher polyploidy levels (>4n) from 72h to 96h post PH indicating that the strong DNA synthesis in these animals after PH predominantly results in higher endoreplication. Conclusion: Our data demonstrates that neither cyclin E1 nor E2 alone is essential for liver regeneration. Depletion of cyclin E1 can largely be compensated presumably by cyclin E2. However, as cyclin E2 depletion leads to earlier and stronger onset of S-phase, higher polyploidy and hepatomegaly, we conclude that cyclin E2 acts as a negative regulator of cyclin E1, whereas our data suggests cyclin E1 as the key player for G1-S phase transition and endoreplication in hepatocytes.

S-ADENOSYL METHIONINE AND METHYLTHIOADENOSINE INHIBIT LIPOPOLYSACCHARIDE-INDUCED TUMOR NECROSIS FACTOR α (TNFα) EXPRESSION VIA MODULATION OF HISTONE METHYLATION

Ainhoa Iglesias Ara, Meng Xia, Komal Ramani, Shelly C. Lu; Medicine, Keck School of Medicine USC, Los Angeles, CA

Background and aim: SAMe has been shown to reduce the expression of pro-inflammatory cytokines such as tumor necrosis factor α (TNFα), which plays a key role in the development of many liver injuries. SAMe and its metabolite methylthioadenosine (MTA) can block lipopolysaccharide (LPS)-induced TNFα expression in RAW cells and Kupffer cells at the transcriptional level without affecting NFκB nuclear binding. However, the exact molecular mechanism(s) of the inhibitory effect remains unclear. While SAMe is a methyl donor, MTA is an inhibitor of methylation and has been shown to inhibit histone 3 lysine 4 (H3K4) methylation. SAMe can convert to MTA spontaneously so that the effect of exogenous SAMe may be mediated by MTA. The aim of our work is to examine whether the mechanism of SAMe and MTA’s inhibitory effect might involve modulation of histone methylation. Methods: RAW cells were pretreated in serum-free medium with 0.75 mM SAMe or 0.5 mM MTA for 16 h. They were then stimulated with LPS (500 ng/ml) or vehicle alone for 4 h, and processed for TNFα gene expression analysis using real-time PCR. The effect of SAMe and MTA on LPS-induced TNFα promoter activity was determined using a luciferase reporter gene assay. In order to study the endogenous chromatin organization of the TNFα promoter, chromatin immunoprecipitation (ChIP) assay was carried out. High-performance liquid chromatography (HPLC) was used to quantify the levels of SAMe and MTA. Results: Consistent with previous studies, we found that LPS induced the TNFα expression by 75.8 fold (±8.0) and the pretreatment with either SAMe or MTA decreased this expression to 18.4 fold (±1.5) or 24.5 fold (±3.7), respectively. The inhibitory effect of SAMe and MTA lies at the transcriptional level as they completely blocked the LPS-induced TNFα promoter activity. Using ChIP assay, we found that LPS increased the binding of trimethylated H3K4 (linked to transcriptional activation) to the TNFα promoter containing two key NFκB sites and this was completely blocked by either SAMe or MTA pretreatment. Exogenous SAMe is unstable and converts spontaneously to MTA, which is stable and more cell permeant. Treatment with both SAMe (0.75 mM) or MTA (0.5 mM) doubled intracellular MTA level, suggesting that the mechanism of SAMe’s inhibitory effect on histone methylation and TNFα expression is likely mediated by MTA. Conclusions: LPS treatment promotes the binding of trimethylated H3K4 to the TNFα promoter. Therapeutic use of SAMe can inhibit LPS-induced gene expression via MTA-mediated inhibition of histone methylation. This aspect of SAMe has not been described and is important in understanding its therapeutic effect.

ADENO VIRAL TRANSFER OF SIRNA AGAINST POLO-LIKE KINASE 1 INHIBITS TUMOR PROGRESSION OF HEPATOCELLULAR CARCINOMA IN VITRO AND IN VIVO

Christina Baehr1, Jörg Haupenthal2, Otto Kollmar3, Bernd Kronenberger1, Simone Kiemayer2, Thomas Pielt2, Oliver Waidmann2, Stefan Zeuzem1, Albrecht Piiper2; 1Department of Medicine I, J. W. Goethe-University Hospital, Frankfurt, Germany; 2Department of Medicine II, University Hospital of Saarland, Homburg/Saar, Germany; 3Department of General, Visceral, Vascular and Pediatric Surgery, University Hospital of Saarland, Homburg/Saar, Germany

Background and Aims: Effective systemic therapy of the hepatocellular carcinoma (HCC) is not available. Polo-kinase 1 (Plk1), a mitosis-associated serine/threonine kinase, is a prime target in carcinomas, in which it is overexpressed. The present
study examined if down-modulation of Plk1 by RNA interference might be a suitable strategy to treat patients with HCC. Methods: Plk1 expression was studied in 7 HCCs and normal liver tissue from the same patient undergoing liver resection by immunoblotting and real-time PCR. Small interfering (si) RNAs raised against Plk1 as well as adenoviral vectors (AdV) encoding short hairpin (sh) RNA against Plk1 (AdV-Plk1), were constructed and examined for their effects on Plk1 expression by immunoblotting, viable cell mass by the MITT test and apoptosis by Hoechst staining in different HCC cell lines and primary hepatocytes. The efficacy of infection of cultured cells as well as of HuH-7 xenografts with AdV upon intravenous injection of the recombinant adenoviral vectors was determined using an AdV encoding β-galactosidase (AdV-LacZ). In addition, the effect of Plk1 down-modulation on HCC progression was studied by intravenous injection of AdV-Plk1 or a control virus in HuH-7 tumors bearing nude mice. Results: Plk1 was strongly expressed in 6/7 HCCs as compared to normal liver tissue from the same patient (average 28.9-fold at the mRNA level). Suppression of Plk1 expression by transfection of siRNAs directed against Plk1 or infection with AdV-Plk1 strongly decreased the viability and increased apoptosis of several cultured HCC cell lines, whereas primary human hepatocytes remained unaffected. Intrahepatic administration of AdV-LacZ into HuH-7 tumor bearing nude mice revealed a high degree of β-galactosidase expression in the tumors. Intravenous administration of AdV-Plk1 caused down-modulation of Plk1 expression and strongly inhibited tumor progression. Conclusions: Plk1 appears to be a suitable target in the treatment of HCC. Systemic adenoviral delivered RNAi-induced down-modulation of Plk1 might be a novel strategy for an effective HCC therapy.

1244 GENE EXPRESSION BASED RECURRENCE PREDICTION OF HBV-RELATED HUMAN HEPATOCELLULAR CARCINOMA

Yoon Jun Kim1, Hyun Goo Woo2, Yong Jin Jung3, Dong Hee Kim4, Bum Joon Park4, Nam-Joon Yi4, Kyung-Suk Suh5, Kuhn Uk Lee6, Dong Hwan Youn7, Snorri S. Thorgerisson8, Hyo-Suk Lee1.1, Department of Internal Medicine, Seoul National University Hospital, Seoul, South Korea; 2Korea Bioinformation center, Korea Research Institute of Bioscience and Biotechnology, Daejeon, South Korea; 3Department of Surgery, Seoul National University Hospital, Seoul, South Korea; 4Laboratory of Experimental Carcinogenesis, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD

Poor prognosis of hepatocellular carcinoma (HCC) is in part due to high rate of recurrence even after “curative resection” of tumors. Therefore, it is axiomatic that development of an effective prognostic prediction model for HCC patients after surgery would at minimum help to identify in advance those who most benefit from the treatment and at best provide new therapeutic strategies for the patients with high risk of recurrence. For the prediction of the risk of recurrence in HCC patients, gene expression profiles were generated in 65 HCC patients with hepatitis B infection. Microarray hybridization was carried out with Human Genome U133A 2.0 chips (Affymetrix, Santa Clara, CA). For the validation of the prognostic reproducibility of this recurrence signature, we applied our recurrence signature directly to an independent gene expression dataset of HCC patients (n=139) [data from Laboratory of Experimental Carcinogenesis (LEC), National Cancer Institute, NIH]. Recurrence associated gene expression signature successfully discriminated between high- and low-risk patients (log-rank test, p=1.9e-6). Comparison of this recurrence signature in independent HCC microarray datasets showed robustness and consistency. Kaplan-Meier plots of HCC subtypes showed a significant difference of recurrence between the subgroups of each individual dataset [SNU data set: p=0.007, LEC dataset: p=0.005, respectively, log-rank test]. Kaplan-Meier analysis on the overall integrated dataset successfully dissected subgroups based on the recurrence rate (p=0.0003). The multivariate analysis, including all the clinicopathological variables and the molecular subtype, showed that only the molecular subtype was significantly associated with tumor recurrence (hazard rate=12.54, 95% CI:3.59-43.76, p<7.30e-5). Genetic network analyses identified SP1 and peroxisome proliferator-activated receptor α (PPARα) as common regulators in the high- and low-risk groups, respectively, suggesting their functional significances for HCC recurrence. In conclusion, we have identified gene expression signature that effectively identifies recurrence subtypes in HCC and our recurrence signature is consistent, robust, and independent of cohorts and experimental platforms of individual studies. The molecular subtype generated by recurrence signature is the most successful predictor even after the clinicopathological features have been considered. Our results might provide novel biological insights into the mechanisms of tumor recurrence.

1245 MITOCHONDRIAL CHOLESTEROL IN HEPATOMA CELLS MODULATES APOPTOSIS SUSCEPTIBILITY AND CANCER THERAPY IN TUMOR XENOGRAFTS

Joan Montero, Albert Morales, Laura Llacuna, Josep M. Ullis, Carmen Garcia-Ruiz, Anna Cell, Jose C. Fernandez-Checa, Liver Unit, Instituto Malalties Digestives, Hospital Clinic, Barcelona, Spain

Cholesterol metabolism is dysregulated in many malignancies, including hepatocarcinoma and stathis have been proposed for cancer therapy. However, experimental data indicate that antitumor properties of statins are primarily due to their blockade of protein isoprenylation and independent of sterol-synthesis inhibition. Mitochondrial cholesterol levels in hepatoma cells correlate with the degree of malignancy. We have previously shown that in vitro cholesterol enrichment of rat liver mitochondria impairs the mitochondrial permeability transition induced by apoptotic stimuli. The AIM of this study was to examine the role of high mitochondrial cholesterol in hepatoma cells in chemotherapy-induced apoptosis and tumor growth. Methods: Rat hepatocarcinoma H35 cells and human hepatoblastoma HepG2 cells were treated with lovastatin or YM-53601, a squaraine synthase inhibitor, for 24 hours examining their susceptibility to thapsigargin, arsine trioxide (ATO), londamine or doxorubicin. Cytochrome c and Smac/DIABLO release from mitochondria was examined by Western Blot. Doxorubicin therapy in vivo was evaluated in tumor xenografts in nude mice by co-treatment or not with atorvastatin (10 mg/kg) or YM-53601 (15 mg/kg). Results: Mitochondria from H35 and HepG2 cells exhibit high mitochondrial free cholesterol levels (5-12 fold) and reduced susceptibility to londamine, ATO, thapsigargin or doxorubicin. Incubation with lovastatin significantly reduced the cholesterol content of mitochondria from H35 cells (6.3 ± 3.5 vs. 13.1 ± 4.4 µg/mg prot.) and HepG2 cells (8.5 ± 2.6 vs. 25 ± 6.4 µg/mg prot.), and increased susceptibility to cell
Moreover, HGF transduction suppresses mice as the result of H-E staining and Azan-Mallory staining. The establishment of liver fibrosis was found in all of AAV5-HGF received mice. AAV5-HGF reached stable HGF expression both in serum and situ zymography were performed. (Results) Mice that received HGF injection, mice were underwent BDL, and then sacrificed 3, 6, 9, and 12 weeks after AAV5-HGF establishment of liver fibrosis, AAV5-HGF was injected once into the portal vein through the splenic hilum. AAV5-LacZ was used as a MOCK. Mice were killed 3, 6, 9, and 12 weeks after treatment. In the present study, we constructed HGF expressing AAV (AAV5-HGF) and examined its effect in two kind of mouse liver fibrosis model. (Method) Two kinds of liver fibrosis model were used in this study. One model was established by carbon tetrachloride (CCl4) administration. CCl4 was administered in Balb/c mice weekly during our experimental schedule. After establishment of liver fibrosis, AAV5-HGF was injected once into the portal vein through the splenic hilum. AAV5-LacZ was used as a MOCK. Mice were killed 3, 6, 9, and 12 weeks after injection to assess therapeutic efficacy. Another model was established by bile duct ligation (BDL). Seven weeks after AAV5-HGF injection, mice were underwent BDL and then sacrificed two weeks after BDL. Liver was removed and underwent histological analysis in both models. Expression of Ets-1, a responsive transcriptional factor of HGF, was also analyzed by Western blotting, and the binding activity of Ets-1 to liver was determined by gel mobility shift assay. To investigate the role of HGF on liver fibrogenesis by CCl4 or BDL, real-time PCR and in situ zymography were performed. (Results) Mice that received AAV5-HGF reached stable HGF expression both in serum and liver for at least 12 weeks. In CCl4 model, significant improvement of liver fibrosis was found in all of AAV5-HGF received mice as the result of HE staining and Azan-Mallory staining. Moreover, HGF transduction suppresses α-SMA expression in mouse livers. These findings were also found in BDL model. In addition, necrotic change was significantly improved by HGF gene transduction. Expression of Ets-1 protein and increased Ets-1 binding ability were found in the liver of mice that were transduced HGF gene. TGF-β, Collagenα1 and TIMP-1 mRNA were significantly suppressed in the liver of AAV5-HGF transduced mice both CCl4 mice and BDL mice. MMP-13 mRNA was significantly increased in the liver of AAV5-HGF transduced mice both CCl4 mice and BDL mice. In situ zymography showed extensive gelatin degradation in liver section of HGF transduced mice compared with control. (Conclusions) Single injection of AAV vector containing HGF gene achieved long term expression of HGF and resolution of mouse liver fibrosis. HGF gene therapy mediated AAV is feasible for the treatment liver fibrosis.

SUBCUTANEOUS VACCINATION WITH DENDRITIC CELLS ENGINEERED TO EXPRESS MAFF AND IL-12 INDUCES INHIBITION OF AFP-EXPRESSING SUBCUTANEOUS HEPATOCELLULAR TUMOR GROWTH IN MICE

Maria A. Gonzalez-Carmona1, Carlo Schneider1, Ingo G. Schmidt-Wolf2, Volker Schmitz1, Tilman Sauerbruch1, Wolfgang H. Caselmann2; 1Internal Medicine I, University of Bonn, Bonn, Germany; 2Bavarian State Ministry of the Environment, Public Health and Consumer Protection, Munich, Germany

Background: Dendritic cells (DC) are professional antigen presenting cells able to prime strongly T-cells against tumor-associated antigens (TAA). However, their potential to induce HCC regression is still limited. AFP is the most relevant TAA of HCC, which can be used as a target for immunological approaches of HCC. IL-12 is the main cytokine for the development of a Th1 immune response. In this study, DC co-transduced with adenoviruses encoding AFP and IL-12 enhanced inhibition of the growth of AFP-expressing HCC in mice. Methods: Four adenoviruses were generated: Ad-mAFP [encoding murine AFP], Ad-IL-12, Ad-GFP-luc (GFP and luciferase) and Ad-LacZ (as control). DC were obtained from bone marrow of C3H-mice and cultured with GM-CSF and IL-4. DC were co-transduced with adenoviruses (MOI 500) on day 6. AFP-expression was detected in Western Blot and CD80, CD86 and CD40 expressions were assayed by flow cytometry. IL-12-expression was detected by ELISA. DC were injected in the left flank of mice s.c. twice at weekly intervals. One week after the last vaccination, a HCC was induced by inoculation of 106 AFP-positive or -negative Hepa129 cells into the right flank of mice. Assessment of transgene expression by DC in vivo was followed using bioluminescence imaging. Results: Ad-mAFP-transduced DC showed a dose-dependent AFP-expression detected already at MOI 100. IL-12-secretion of DC, which were transduced with Ad-IL-12 was significantly enhanced compared to control or Ad-AFP-transduced DC. CD80, CD86 or CD40 expressions were not reduced by adenoviral transduction. Vaccination with AFP-expressing DC could inhibit significantly the growth of AFP-expressing HCC, but not of AFP-negative tumors, indicating AFP-specificity of the immune response. Vaccination with Ad-IL-12/Ad-mAFP co-transduced DC inhibited significantly the tumor volume compared to controls, vaccinated with Ad-AFP or Ad-LacZ-transduced DC. Two weeks after tumor induction, the hepatocellular carcinoma was significantly (p<0.05). Using Ad-GFP-luc-transduced DC, a delivery of transgene expression of adenoviral transduced DC into the ipsilateral lymph nodes was observed in vivo. Conclusions: Our data show that s.c.-vaccination with Ad-IL-12/Ad-AFP-transduced DC can significantly enhance the inhibitory effects of Ad-AFP-transduced DC against AFP-positive HCC in mice. Moreover, we observe a migration and delivery of transgene expression of adenoviral transduced DC into secondary lymphoid tissues, suggesting that
interaction of TAA-expressing DC with Th1-lymphocytes takes place in the lymph nodes.

TRANSFORMING GROWTH FACTOR-β GENE EXPRESSION SIGNATURE PREDICTS CLINICAL OUTCOME IN CANCER

Cedric Coulouarn, Valentina M. Factor, Snorri S. Thorgeirsson; Laboratory of Experimental Carcinogenesis, NIH/NCI, Bethesda, MD

Hepatocellular carcinoma (HCC) is one of the most common cancers in the world. The clinical heterogeneity of HCC and the lack of good diagnostic markers and treatment strategies have rendered the disease a major challenge. Patients with HCC have a highly variable clinical course indicating that HCC comprises several biologically distinctive subgroups. We hypothesized that the prognostic variability likely reflects a molecular heterogeneity of tumors. In the process of testing this hypothesis, we have asked if a gene expression signature specific for TGF-β signaling pathway could refine the diagnosis and/or prognostic predictions of HCC patients. Since TGF-β exhibits tumor stage dependent suppressive (i.e. growth inhibition) and oncogenic (i.e. invasiveness) properties, a TGF-β gene expression signature may contain gene sets characteristic for these properties and thus be relevant for the molecular classification of the tumors. Applying a comparative functional genomic approach we demonstrated that temporal TGF-β gene expression signatures established in mouse primary hepatocytes successfully discriminated distinct subgroups of HCC. The TGF-β positive cluster highlighted two independent, early (1-2 hours) and late (4-24 hours), TGF-β signatures. To evaluate the clinical significance of TGF-β signature in the molecular classification of HCC, we then compared the distribution of several clinical and pathological variables between HCC harboring early or late TGF-β signatures. Kaplan-Meier plots and log-rank statistics indicated that the patients with a late TGF-β signature showed a significantly shorter mean survival time (16.2 ± 5.3 months) compared to the patients with an early (60.7 ± 16.1 months) TGF-β signature. Also, tumors expressing late TGF-β responsive genes displayed an invasive phenotype and an increased tumor recurrence. Furthermore, we demonstrated that the TGF-β gene expression signature possess a predictive value for tumors other than HCC and therefore open new avenues for novel TGF-β based therapeutic approaches.

A UNIQUE METASTASIS-RELATED MICRORNA EXPRESSION SIGNATURE IS A PROGNOSTIC INDICATOR OF SURVIVAL AND RECURRENTENCE IN HEPATOCELLULAR CARCINOMA

Anuradha Budhu1, Hu-Liang Jia1,2, Marshonna Forgues1, Chang-Gong Liu3, David Goldstein4, Amy Lam5, Krista Zanetti1, Qing-Hai Ye2, Lun-Xiu Qin1, Carlo Croce1, Zhao-You Tang3, Xin Wang1; 1Laboratory of Human Carcinogenesis, National Cancer Institute, Bethesda, MD; 2Liver Cancer Institute and Zhongshan Hospital, Fudan University, Shanghai, China; 3Department of Molecular Virology, Immunology and Medical Genetics and Comprehensive Cancer Center, Ohio State University, Columbus, OH; 4Office of Science and Technology Partnerships, Center for Cancer Research, National Cancer Institute, Bethesda, MD; 5EMMS Corporation, Rockville, MD

Background: MicroRNAs (miRNAs) have been utilized as biomarkers to distinguish cancers from their normal counterparts. Hepatocellular carcinoma (HCC) is an aggressive cancer with a dismal outcome largely due to metastasis and post-surgical recurrence. Objectives: We investigated whether the expression of unique miRNAs are associated with metastatic HCC and correlate with prognosis and recurrence. Methods: We examined the miRNA expression profiles of 482 cancerous and non-cancerous specimens from radical resection of 241 HCC patients. Using a supervised algorithm, we built a miRNA metastasis signature based on 131 clinically well-defined metastatic and non-metastatic HCC specimens, which was then used to predict the prognostic outcomes of the remaining 110 independent HCC specimens. Results: A unique 20-miRNA signature could significantly predict (p<0.001) 29 primary HCC tissues with venous metastases from 102 metastasis-free solitary tumors with 10-fold cross validation which significantly correlated with survival (p=0.005). However, significant miRNAs could not be identified from the corresponding non-cancerous hepatic tissues. The tumor miRNA signature was a significant independent predictor of patient survival (p=0.009) in 110 additional independent HCC specimens. The signature was also significantly associated with both survival and relapse in 89 early stage HCC (p=0.022 and 0.002, respectively). This signature was associated with a two-fold increase in death for cases predicted to be metastatic. Conclusions: Specific miRNAs exceed the prognostic capacity of current staging systems for HCC. We suggest that a simple method to profile certain miRNAs may have clinical utility for advanced identification of HCC patients who are likely to develop metastases/recurrence and subsequent selection of candidates for appropriate treatment.

HUGL-2, THE HUMAN HOMOLOGUE OF THE DROSOPHILA TUMOR SUPPRESSOR LGL, IS REGULATED BY EGF AND SNAIL, A PRIME REGULATOR OF EPITHELIAL-MESENCHYMAL TRANSITION (EMT)

Tim Zimmerman1, Anubha Kashyap1, Urs Hartmann1, Gerd Otto2, Peter R. Galle1, Susanne Strand1, Dennis Strand1; 11st Department of Medicine, University of Mainz, Mainz, Germany; 2Department of Transplantation Surgery, University of Mainz, Mainz, Germany

Background: Hugl-1 and Hugl-2, the human homologues of Drosophila lethal giant larvae (lgl), are highly conserved tumor suppressor genes encoding cytoskeletal proteins. The human lgl
polarity gene, Hugl-2, is involved in development of normal epithelial differentiation and maintenance of cell integrity and adhesion. Reduced expression of Hugl contributes to tumor progression in various tissues. The aim of this study was to identify regulatory elements in the Hugl-2 promoter to better understand the transcriptional regulation of Hugl-2 during tumor progression especially in human hepatocellular carcinoma. Here we report the regulation of Hugl-2 by EGF and the transcription factor Snail. Methods: Hugl-2 promoter region was identified by using the MatInspector program and cloned in pGL3-basic luciferase vector. We examined the promoter activity and activities of truncated forms in transiently transfected HepG2 cells and primary hepatocytes after treatment with different agents. Regulating transcription factors and their sequence binding sites were identified. We co-transfected Snail cDNA expression plasmids with the Hugl-2 promoter. Snail binding sites were mutated. To detect direct binding of Snail on the promoter Chromatin immunoprecipitation was performed. Results: Northern Blot analyses of Hugl-2 showed that the gene is mainly expressed in the liver and pancreas, whereas Hugl-1 is mainly expressed in brain with absent expression in liver. Hugl-2 might be implicated in hepatic and pancreatic processes. Promoter analyses showed high basal Hugl-2 promoter activity in cell lines and primary hepatocytes. Searching for conserved transcription factor binding sites and regulatory pathways, we identified EGF and Snail as suppressors of Hugl-2 promoter activity, suggesting that Hugl-2 is regulated by EGF and Snail. Down-regulation of Hugl-2 by these factors might result in a reduction of cell adhesion and therefore in an acceleration of tumor progression. Co-transfection experiments with Snail cDNA expression plasmids and the Hugl-2 promoter construct revealed a strong and dose dependent repression of the Hugl-2 promoter by Snail. Using Hek-293 cell lines stably expressing Snail, we could show not only repression of the Hugl-2 promoter plasmid but also of the endogenous Hugl-2 promoter. Chromatin immunoprecipitation assays revealed a direct binding of Snail on the Hugl-2 promoter. Conclusions: The tumor suppressor gene Hugl-2 is transcriptionally regulated by EGF and Snail. We identified molecular targets in the Hugl-2 promoter which may play a role in the downregulation of the Hugl-2 tumor suppressor gene during progression of human hepatocellular carcinoma.

1251 ENHANCED RETINOIC ACID-INDUCED APOPTOSIS IN HEPATOCELLULAR CARCINOMA CELLS VIA ER STRESS-RELATED JNK ACTIVATION IS ATTENUATED BY HYPOXIA INDUCTION OF CRABP-II
Jung-Hwan Yoon1, Jeong-Hoon Lee1, Goh Eun Chung1, Bo Hyun Kim1, Sun Jung Myung1, Jong In Yang1, Won Kim1, Yoon Jun Kim1, Kyung-Suk Suh2, Hyo-Suk Lee2. 1Department of Internal Medicine and Liver Research Institute, Seoul National University College of Medicine, Seoul, South Korea; 2Department of Surgery, Seoul National University College of Medicine, Seoul, South Korea

Background/Aims: Hepatocellular carcinoma (HCC) is characterized by hypervascularization and its growth is tightly linked to the neovascularization. However, advanced infiltrative HCCs seldom show hypervascularity, though they are more rapidly growing than mass-forming types. Therefore, hypoxia is most likely to activate survival signaling in HCC cells. In this study, we attempted to find an agent which can induce cell death more efficiently in hypoxic HCC cells than in normoxic cells.

Methods: Human HCC cell lines were used in this study. RNAs extracted from cells cultured either in a normoxic or hypoxic condition were used for cDNA microarray analysis. Cell growth was assessed using the MTS assay and the apoptotic cell death was measured by DAPI staining. Apoptotic signaling cascades and kinase signaling were explored by immunoblot analysis. The occurrence of ER stress was evaluated with immunoblot for phospho-eIF2α.

Results: Out of many molecules up-regulated in hypoxic cells, we found that cellular retinoic acid binding protein II (CRABP-II) signal was significantly increased. Hypoxia induction of CRABP-II protein expression was confirmed by immunoblot analysis. Since CRABP-II is a binding partner of all-trans-RA (RA) and RA can induce cellular apoptosis, we next treated HCC cells with RA. HCC cell growth was suppressed following RA treatment. In particular, this growth suppression was significantly enhanced in hypoxic cells as compared to normoxic cells. RA treatment induced HCC cell apoptosis by activating caspase 9, and this was more enhanced in hypoxic cells than in normoxic cells. This enhanced caspase 9 activation was associated with enhanced Jun N-terminal kinase (JNK) activation in these hypoxic cells. ER stress, which can lead to pro-apoptotic JNK activation, was more activated in hypoxic cells following RA treatment as compared to normoxic cells. To clarify the role of CRABP-II induction by hypoxia in RA-induced apoptosis, cells were then transfected with CRABP-II-specific siRNA. Cells with reduced CRABP-II expression showed more enhanced RA-induced JNK activation and cellular apoptosis than control cells.

Conclusions: These results demonstrate that RA induces cellular apoptosis more efficiently in hypoxic cells than in normoxic cells via enhanced ER stress-related JNK activation, and that CRABP-II induction by hypoxia attenuates RA-induced apoptosis in hypoxic HCC cells. Therefore, this RA/CRABP-II signaling may therapeutically be useful in the treatment of advanced hypovascular HCCs, which are exposed to hypoxic environment.

1252 INVESTIGATION OF THE ROLE OF GLYPICAN-3 IN RAT HEPATOCYTE GROWTH AND LIVER REGENERATION
Bowen Liu, William C. Bowen, Aaron W. Bell, Shirish Paranjpe, Wendy M. Mars, Kari N. Nejak-Bowen, Jianhua Luo, George Michalopoulos; Pathology, University of Pittsburgh Medical Center, Pittsburgh, PA

Glypicans are heparan sulfate proteoglycans (HSPGs) that are bound to the cell surface through a glycosylphosphatidylinositol (GPI) anchor. Five members of the glypican family have been identified in mammals, which share different levels of homology and expression patterns. Among these glypicans, it has been reported that mutations in the human glypican 3 (GPC3) gene are associated with the Simpson-Golabi-Behmel (SGB) syndrome, which is an X-linked disorder characterized by pre- and postnatal overgrowth. GPC3 is reported to be over-expressed in human hepatocellular carcinoma (HCC) and several hepatoma cell lines. Whether GPC3 is involved in liver regeneration and hepatocyte proliferation is still unknown. We investigated its role in regenerative liver using the 2/3rd partial hepatectomy models in rats. Results from RT-PCR showed that expression of GPC3 is upregulated in liver starting from 3 hours after partial hepatectomy. However, GPC3 protein on the membrane significantly decreases after hepatectomy through day 2 and then returns to normal levels by day 5. Examination of GPC3 levels in primary hepatocyte cultures revealed that GPC3 is upregu-
lated from day 7, when the process of proliferation slows down. Yeast two hybrid assay was performed to investigate its potential interacting protein and pathway. We found several interesting target proteins such as CD81 and Hrs. The interaction test assay and pathway study has been carried out for CD81, a member of tetraspan family and reported to involve in cell proliferation. RT-PCR result showed that in regenerative liver, CD81 RNA level decreases after heptectomy through day 2 and then returns to normal levels by day 5, which corresponds to the changes of GPC3 protein level. Immunofluorescence and immunohistochemistry study showed that both CD81 and GPC3 localize on the cell membrane of hepatocytes. Further study will include GPC3 transgenic mice screening and study, and in vivo and in vitro growth study. We hypothesize that GPC3 negatively regulate cell growth and may interact with CD81.

1253
THE ROLE OF NF-κB ACTIVITY IN THE ANTIVIRAL ACTION OF INTERFERON
Lawrence Pfeffer; UTHSC, Memphis, TN

The role of NF-κB activity in the induction of IFN's antiviral action was examined in MEFs that either had normal NF-κB function (WT MEFs), or had a germline disruption of both p50 and p65 NF-κB proteins (p50/p65-DKO MEFs). It was very interesting that p50/p65-DKO MEFs were more sensitive to the antiviral action of IFN against influenza virus as compared to WT MEFs. For example while IFN (100 U/ml) only results in a ~8-fold reduction in influenza virus titer in WT MEFs, a 100-fold lower IFN concentration (1 U/ml) induced an equivalent antiviral effect in DKO MEFs. Thus the IFN-activated NF-κB pathway may attenuate the induction of antiviral activity by IFN. To characterize the role of NF-κB in regulating IFN-stimulated gene (ISG) expression, we compared gene expression in WT and p50/p65-DKO MEFs treated in the presence or absence of IFN by bioinformatic approaches. The induction by IFN of a subset of genes encoded GTP-binding and antigen presentation proteins was regulated by NF-κB. The NF-κB-regulated GTP-binding ISGs included the 65-67 kDa guanylate-binding proteins (Gbp 1 and Gbp2), the Mx proteins (Mx1 and Mx2), and the 47-kDa GTPase Ifi47 [also called lrg47]. GBP proteins play important roles in resistance to viruses, as well as intracellular protozoa and bacteria. The NF-κB-regulated antigen presentation ISGs (Tap1, Tap2, Psmb9/Lmp2, and Psmb8/Lmp7) are involved in degrading intracellular proteins into antigenic peptides, and contribute to the transport of these peptides to endoplasmic reticulum where they bind to the assembled MHC class I molecules. We found that Gbp1, Ifi47, Mx1, Mx2, Tap1, Psmb9/Lmp2 and Psmb8/Lmp7 were induced by IFN to a greater extent in NF-κBKO MEFs than in WT MEFs, while Gbp2 and Tap2 were induced to a greater extent in WT MEFs than in p50/p65-DKO MEFs. These findings suggested that NF-κB differentially regulates the expression of a subset of ISGs that play important roles in innate immunity. To further investigate the induction of NF-κB-regulated ISGs, qPCR was performed for Ifi47, Tap1 and Mx1 using RNA from WT and p50/p65-DKO MEFs and confirmed the microarray results. The effect of NF-κB on regulation of these ISGs is specific since the expression profile of another ISG, IRF1, was not regulated by NF-κB, and did not reflect altered JAK-STAT signaling since STAT2 activation was similar in WT and p50/p65-DKO MEFs. Our results indicate that NF-κB selectively attenuated the transcription of a subset of ISGs.

GANGLIOSIDE GD3 SYNTHASE OVEREXPRESSION SENSITIZES HUMAN HEPATOMA CELLS TO HYPOXIA BY SUPPRESSING THE NUCLEAR FACTOR-κB-DEPENDENT SURVIVAL PATHWAY
Josep M. Lluís1, Albert Morales1, Scott Welford2, Amato Giaccia2, Jose C. Fernandez-Checa1, 1Liver Unit, Instituto Malalties Digestives, Hospital Clinic, IDIBAPS, CISC, Barcelona, Spain; 2Division of Radiation and Cancer Biology, Stanford University, Stanford, CA

Hypoxia is a common feature of solid tumors which regulates malignant progression and responsiveness to therapy. The adaptation to hypoxia is mediated by mitochondrial reactive oxygen species (ROS) generation that contributes to survival of cancer cells, angiogenesis, vascularization, glycolytic ATP and tumor invasion through NF-κB and HIF-1α activation. Ganglioside GD3 is a lipid death effector due to its interaction with mitochondria and inactivation of NF-κB-dependent survival pathways. We have recently shown that NF-κB plays a critical role in the survival of hepatoma cells during hypoxia. Thus, the aim of our work was to examine the survival of hepatoma cells that overexpress GD3 during hypoxia. Methods. GD3 synthase full-length cDNA (1.2 kb) was cloned into pcDNA3.1D/V5-His-TOPO®. Hep3B were transfected with pcDNA3M-GD3 (Hep3B-GD3) or pcDNA3 (no insert, Hep3Bwt) and selected during 3-4 weeks based on expression of GD3 synthase, its enzymatic activity and GD3 levels. Hypoxia (2%) was induced in Hep3B cells for 24-72 hours. NF-κB and HIF-1α transactivation were measured by luciferase reporters. Results. Immunostaining analyses indicated that GD3-expressing Hep3B clones accumulated GD3 both at the cell surface and in internal membranes, including mitochondria. These cells did not exhibit changes in morphology, growth and apoptosis as compared to Hep3Bwt during normoxia. However, the exposure of Hep3B-GD3 cells to 2%O2 elicited a time-dependent decrease in cell survival reaching 55% at 72 hours while in Hep3Bwt was 90%. This was accomplished by greater ROS generation (1.5-2 fold) in Hep3B-GD3 versus Hep3Bwt. Hypoxic NF-κB activation observed in Hep3Bwt (2.3 fold) was abrogated in Hep3B-GD3 cells (1.2-1.5 fold) whereas HIF-1α levels (6 fold versus normoxia) remained similar in both clones. We next, focused on the regulation of Mn-SOD, a known κB-controlled antioxidant enzyme. Interestingly, hypoxia induced Mn-SOD protein and mRNA levels (2-3 fold, respectively) in Hep3Bwt that were reduced upon NF-κB downregulation in Hep3B-GD3 (1.2-fold). Moreover, MnTBAP, a SOD mimetic, reduced ROS generation and protected Hep3B-GD3 cells against 2%O2 at 72 hours (viability of 75%). Conclusions. Endogenous expression of ganglioside GD3 sensitizes Hep3B cells to hypoxia through suppression of inducible κB-dependent antioxidant Mn-SOD resulting in cytotoxic ROS overgeneration. These findings suggest that ganglioside GD3 may be useful in cancer gene therapy as a sensitizing agent in hypoxic-resistant cancer cells.

1255 TRANSLATIONAL CONTROL OF GENE EXPRESSION DURING LIVER DIFFERENTIATION

Desiree M. Espiet, Richard Stockert; Department of Medicine, Albert Einstein College of Medicine, Liver Research Center, Bronx, NY

Background: Our early studies defined expression of the asialoglycoprotein receptor (ASGR) as a biochemical marker of hepatocyte terminal differentiation. Unlike most differentiation-dependent genes whose expression is regulated at the transcriptional level, developmental control of ASGR expression is at the translational level. The AIM of the present study was to characterize the molecular elements that govern differentiation-dependent ASGR expression and to determine if common elements control both in vivo and in vitro expression.

Methods and Results: Insertion the ASGR mRNA 5' untranslated region (UTR) upstream of the firefly luciferase AUG start site reduced the level of firefly luciferase activity by almost 2.5 fold in proliferating less well defined HuH-7 cells as compared to well differentiated quiescent cells. Electrophoretic mobility shift assay (EMSA) was used to confirm the presence of RNA binding protein (RBP) or trans-acting factor responsive to the state of hepatocellular differentiation. The observed 4x decrease in the specific activity of a trans-acting factor in quiescent HuH-7 suggests a derepression pathway was responsible for enhanced ASGR translation during hepatocellular differentiation. A capped, cRNA transcript containing the full-length ASGR was transcribed and translated in vitro using a wheat germ lysate in the presence of extracts from HuH-7 cells grown to low or high density. Cytosolic protein isolated from cells at low density inhibited translation over 80% while protein from high density cells was nearly inactive. A 10x molar excess of the 5'UTR ASGR mRNA fragment added as a decoy to the low density cell lysate restored translation to nearly 80%, confirming the presence of the cis-acting element. Characterization of ASGR protein and RNA expression during mouse liver development indicates that while there is an increase in transcript number during the transition between 18 day embryos and newborn mice it does not result in a concomitant increase in ASGR protein, suggesting a repression of translation during this period of liver development. EMSA was used to confirm the presence of common RBPs responsive to the state of hepatocellular differentiation. Inhibited a protein directed gel shift by preincubation of human 5'UTR with mouse cytosol strongly supports the contention that common structural elements govern translational regulation of ASGR.

Conclusion: Taken together, the results obtained from cell culture and in vivo experiments provide support for the notion that common RBP(s) interact with the ASGR 5'UTR secondary structure to play an essential regulatory role in differentiation-dependent translation.

1256 IN VIVO SUPPRESSION OF MAFA mRNA WITH SIRNA AND ALTERATION OF THE GENE EXPRESSION PROFILE, ESPECIALLY OF ADIPOCYTOKINE GENES, IN MOUSE LIVER ANALYZED BY THE MICROARRAY METHOD

Mariko Tsujiya1, Atsushi Maeda1, Junko Tanaka1, Ken Tsujiya2; 1Institute of Geriatrics, Tokyo Women's Medical University, Tokyo, Japan; 2Department of Medicine IV, Tokyo Women's Medical University, Tokyo, Japan

One of the large maf molecules, mafa, is a strong transactivator of insulin gene transcription in pancreatic β cells. We previously reported that suppression of the mafa mRNA level in the mouse pancreas by the RNA interference technique resulted in down-regulation of adipocytokine genes in addition to the genes encoding insulin and glucagon. Mafa is likely to be related not only to the formation of pancreatic islets but to adipocytokine regulation. On the other hand, there have been several reports that mafa contributes to liver cell transdifferentiation to insulin-producing cells in combination with several transcriptional factors, suggesting a potential role of mafa in cell differentiation in the liver. In view of the role of mafa in the pancreas, the present study investigated whether reduction of the mafa mRNA level in vivo liver would induce an alteration of the gene expression profile, including adipocytokine genes. An expression vector carrying synthetic mafa siRNA was rapidly injected via the tail vein of 8-week-old mice by the hydrodynamic method, and the gene profile was analyzed with a microarray system (Affymetrix). The level of each transcript was confirmed by real-time PCR. Interference with the mafa mRNA level in the liver by siRNA resulted in a 70% reduction. The microarray analysis showed that the suppression of mafa mRNA expression in the liver caused down-regulation of genes related to lipid metabolism or cell growth, including the genes coding insulin like growth factor binding protein-1, thyroid hormone responsive spot 14, and fatty acid synthase, and up-regulation of genes coding heat shock protein 68, Onecut1/HNF-6, and Slc25a30. Both Onecut1/HNF-6, a transcription factor activated during liver development and pancreatic duct formation, and Slc25a30/KMCP1, a mitochondrial carrier protein induced during fasting and cell regeneration in the kidney, were significantly up-regulated, 2.7-fold and 3.9-fold respectively, by real-time PCR. Real-time PCR also showed that expression of adipogenic genes, such as adiponectin and adiponectin, was significantly down-regulated. Thus, mafa may have potential roles in adipocytokine regulation in the liver, for example, stellate cell differentiation (dedifferentiation) may occur through adipogenic genes regulation, or working in tandem with other transcription factors, in which mafa may be involved. In summary, mafa may be implicated in cell differentiation and the regulation of expression of some adipocytokines in the liver, the same as in the pancreas.

1257 AUGMENTER OF LIVER REGENERATION (ALR): THE FACTOR THAT REGULATES HEPATOCYTE APOPTOSIS IN LIVER REGENERATION AFTER PARTIAL HEPATECTOMY

Lorenzo Polimeni, Barbara Pesetti, Emanuele Annoscia, Marcella Margiotta, Floriana Giorgio, Thomas Lisowsky, Annacinzia Amoruso, Antonio Francavilla; DETO, Università degli Studi di Bari, Bari, Italy

Background: Hepatocyte apoptosis is an important process in the fine-tune recovery of liver mass after major resection. Still unknown are the factors that control this event among the GFs and cytokines upregulated during liver regeneration. Aims: To identify the factor/s that control hepatocyte apoptosis in the animal model of liver proliferation after 70% partial hepatectomy. Materials/Methods: All the animals used underwent 70% partial hepatectomy. Recombinant Hepatocyte Growth Factor (rHGF) and Augmenter of Liver Regeneration (rAlrp) were used. We first determined serum profiles of HGF and ALR, recording a peak, for both GFs, at the 18th hr after surgery. We then administered to the animals rHGF or rAlrp, every six hrs, starting at 18th hour until 48 hrs after PH. On liver samples, hepato-
Hepatocyte proliferation (L.I.), apoptosis (TUNEL) and apoptotic genes (Bcl-2, Bax, Casp-3) mRNA levels were determined. Results: Hepatocyte proliferation in control animals was: 24hrs L.I.=22±3.5, 36hrs L.I.=21±2.4 and 48hrs L.I.=13±2.5. rHGF injection increased hepatocyte proliferation at 24 hours (L.I.=33±4), 36 hours (L.I.=28±3) and at 48 hours (L.I.=18±2.7). rAlp injection had no effect on hepatocyte proliferation. Apoptotic profile of control animals was 7.5±1.8, 3.0±0.9 and 4.1±1.2 apoptotic hepatocytes/1000 hepatocytes respectively at 24, 36 and 48 hours. rHGF administration did not produce any significant effect on hepatocyte apoptosis, while rAlp injection reduced it at 24 hours (1.2±0.5) and at 48 hours (2.2±0.7). Apoptosis-related genes showed an up-regulation of the anti-apoptotic gene (Bcl-2) and a down-regulation of the pro-apoptosis genes (Bax and Casp 3) (Fig). Conclusions: The present data demonstrate that ALR is one/ the factor responsible of hepatocyte apoptosis control in liver regeneration after partial hepatectomy by inducing anti-apoptotic genes and down-regulating pro-apoptotic genes.

1258
COBALT PROTOPORPHRYN BINDS TO BACH1, A TRANSCRIPTIONAL REPRESSOR OF HEME OXYGENASE 1 GENE

Weihong Hou1,2, Ying Shan1,2, Richard W. Lambrecht1,2, Jianyu Zheng1,2, Susan E. Donohue1,2, Herbert  L. Bonkovsky1,4; 1Department of Medicine, University of Connecticut Health Center, Farmington, CT; 2The Liver-Biliary-Pancreatic Center, University of Connecticut Health Center, Farmington, CT; 3Department of Pharmacology, University of Connecticut Health Center, Farmington, CT; 4Carolinas Medical Center, Charlotte, NC

Background/Aims: Heme Oxygenase 1 (HO-1) catalyzes heme degradation, generating ferrous iron, carbon monoxide and biliverdin, which have anti-oxidant and anti-inflammatory activities in vivo. It has been reported that enhancement of HO-1 in the liver suppresses the development of fibrosis associated with recurrent liver injury, including chronic viral hepatitis, alcohol abuse, autoimmune diseases and hereditary metabolic disorders. We found previously that cobalt protoporphyrin (CoPP) markedly up-regulates HO-1 in human liver cells; however, little is known about the mechanism by which this occurs. Bach1 is a basic leucine zipper (bZip) mammalian transcriptional repressor of HO-1. Heme is known to bind Bach1C (the C-terminal heme binding region of Bach1 that possesses four dipeptide cysteine-proline (CP) motifs), leading to its transport from nuclei to cytoplasm and thus to up-regulation of HO-1 gene expression by Nr4f2 and other small Maf proteins. The Aim of this study was to understand the binding of CoPP and other selected metalloporphyrins to Bach1. Methods: pET SUMO expression system (Invitrogen) was used to express Bach1C as a fusion protein with a small ubiquitin-related modifier (SUMO), in E.coli. The fusion protein was purified by Ni-NTA affinity chromatography and cleaved by a SUMO-specific protease to obtain native Bach1C, which was further purified by Ni-NTA affinity chromatography. CoPP was incubated with Bach1C for 30 min, followed by removal of free CoPP by dialysis. The resulting mixtures were scanned using UV-visible spectroscopy to observe the typical Soret band of protein-bound metalloporphyrins. Results: The purified Bach1C-SUMO fusion proteins were a brownish color and displayed a typical hemoprotein spectrum with Soret bands, suggesting the presence of endogenous heme in the purified Bach1C-SUMO protein. Upon incubation of Bach1C with CoPP, a Soret band with a peak at 420 nm was observed. Mutations of all of the CP motifs in Bach1C abrogated its interaction with CoPP as measured by spectroscopy. These results suggest that CoPP binds to the four CP motifs as heme does. We did not detect the binding of Bach1C to zinc- or tin mesoporphyrin. Conclusion: CoPP directly binds to Bach1C, thus presumably regulating its DNA–binding activity. These and other recent results (Hou et al, Gastroenterology 2007; 132:A825) indicate that CoPP may hold promise as a potential therapeutic agent to prevent or ameliorate hepatic fibrogenesis. Acknowledgement: Supported by NIH grant RO1 DK38825

1259
POSSIBLE ROLE OF TYROSINE KINASE INHIBITOR AND PROTEASOME INHIBITOR FOR HCC TREATMENT

Tomomi Kogiso1, Hikaru Nagahara1,2, Keiko Shiratori2; 1Sanno Hospital, International University for Health and Welfare, Tokyo, Japan; 2Institute of Gastroenterology, Tokyo Women’s Medical University, Tokyo, Japan

Aim: It has been reported that proteasome inhibitors or tyrosine kinase inhibitors can inhibit proliferation of several cancers, suggesting their therapeutic possibility or efficacy. Here, we determined whether these two type of inhibitors could become effective therapeutic tools for human hepatocellular carcinoma (HCC) through induction of apoptosis or cell cycle arrest. Materials and Methods: Human HCC cell lines, HuH7, HepG2 and HuH2 cells, were treated with either MG132, a proteasome inhibitor, or PD166289 (PD), a tyrosine kinase inhibitor. The cell cycle profile was determined by FACS analysis at each time point, and cell population at sub-G1 phase was defined as the apoptotic cells. The expression level of proteins was analyzed by western blotting; in addition physical interaction of p21Cip1 and CDK family was confirmed by IP-western technique. In order to knock down p21Cip1 or Wee1 kinase, we transfected the plasmid vector which expressed the short interfering RNA (siRNA) directed against their gene. The immunostaining was performed by using anti-Wee1 kinase antibody in
human HCC tissues which were surgically resected and used under the informed consent. Results: MG132 induced G2/M cell cycle arrest within 8 h after addition of MG132 and in a dose dependent manner. The Wee1 kinase induction and phosphorylation of Tyr15 in CDC2 was associated with the G2/M cell cycle arrest. Pretreatment with Wee1 kinase inhibitor could release cells from G2/M cell cycle arrest. p21Cip1 was simultaneously up-regulated in MG132-treated HuH7 cells, but was not p27Kip1. This p21Cip1 could not physically bind to CDC2, moreover, HuH7 cells knocked down p21Cip1 still showed G2/M cell cycle arrest by MG132 treatment. PD treatment induced apoptosis in cells associated with de-phosphorylation of Tyr15 in CDC2 leading to apoptosis. The PD-mediated apoptosis was completely inhibited by pretreatment with Roscovitine or Alsterpaulone, CDC2 inhibitors. The immunostaining of Wee1 kinase revealed positive HCC cells in 36% of poorly to moderately-differentiated HCC tissues. Conclusion: Proteasome inhibitor induced G2/M cell cycle arrest, while PD treatment executed apoptosis in HCC cell lines. From the results of immunostaining, down regulation of Wee1 kinase might be a possible approach to growth suppression of HCC by induction of apoptosis.

1260 GENE EXPRESSION PROFILE OF PERIPHERAL BLOOD MONONUCLEAR CELLS MAY REFLECT THOSE OF TUMOR-INFILTRATING LYMPHOCYTES IN HEPATOCELLULAR CARCINOMA

Yoshio Sakai1, Masao Honda1, Haruo Fujinaga2, Isamu Tatsumi2, Shuichi Kaneko1; 1Gastroenterology, Kanazawa University Hospital, Kanazawa, Japan; 2Disease Control and Homeostasis, Kanazawa University, Kanazawa, Japan

Peripheral blood mononuclear cells (PBMCs) are circulating in the systemic blood flow and interacting with each organ. Infiltrating lymphocytes are often found in cancerous tissues including hepatocellular carcinoma (HCC). We have explored gene expression profile of infiltrating lymphocytes in HCC or non-cancerous liver tissues. Furthermore, we have examined whether gene expression profile of PBMCs of type C cirrhosis (LC) patients with HCC was different from those without HCC and assessed how gene expression of PBMCs in HCC patients correlated with that of HCC-infiltrating lymphocytes. [Methods] Enrolled were 32 patients of LC and 30 patients of LC with HCC (Age:64.9+/-10.3, 70.3+/-9.0 years old, male/female=13/19, 12/18, respectively). Another series of 12 cirrhotic patients underwent surgery for HCC, and infiltrating lymphocytes in HCC as well as non-cancerous liver tissues were isolated by laser capture microdissection. RNAs were extracted from obtained cells, amplified, labeled with Cy5 dye, mixed with Cy3-labeled reference RNA and hybridized to DNA microarrays (AceGeneHuman30K, HitachiSoft). Intensity was obtained, normalized, and analyzed using BRB-ArrayTools (NCBI) and MetaCore (GeneGo). Retrieved gene expression database for major leukocytes from Gene Expression Omnibus (NCBI) were also used for data analysis. [Results] Up-regulated genes in HCC-infiltrating lymphocytes were mostly involved in retrieved gene expression database of macrophages and helper T cells, and this constituent was confirmed by immunohistochemistry. Gene expression profiles of PBMCs were significantly discernable in context of HCC or LC patients by unsupervised clustering and supervised learning method. Comparison of gene expression for infiltrating lymphocytes in HCC and non-cancerous liver tissues identified 320 significant genes (p<0.01) and they discerned gene expression of PBMCs of patients relying on existence of HCC with 82% accuracy. Many biological processes were shared with significant genes of HCC-infiltrating lymphocytes and PBMCs in HCC patients, such as ubiquitin-proteasome, response to hypoxia and oxidative stress for up-regulated genes etc. The commonly up or down-regulated genes in HCC-infiltrating lymphocytes as well as PBMCs of HCC patients constructed gene network with 3 pivotal genes, nucleophosmine, SMAD3, and PCNA pertaining to proteasome, cell cycle, anti-oxidative genes. Interestingly, it involved FOXP3 as up-regulated and JAK3 as down-regulated genes, implying disturbed immunity. [Conclusion] Infiltrating lymphocytes in local HCC tissues might have influence on PBMCs and the usage of gene expression profiles of PBMCs could discern HCC in LC patients.

1261 HUMAN GANKYRIN OVEREXPRESSION DOWNREGULATES P53 EXPRESSION AND PROMOTES CELL PROLIFERATION IN ZEBRAFISH

Seung Kew Yoon, So Yeon Kim, Wonhee Hur, Jung-Eun Choi, Daniel Kim, Lian-Shu Piao, Chan Ran You, Hyun Young Woo, Soung Won Jeong, Si Hyun Bae, Jong Young Choi; Department of Internal Medicine, The Catholic University of Korea, Seoul, South Korea

Background and Aims: Gankyrin is an oncoprotein containing seven ankyrin repeats that is overexpressed in hepatocellular carcinoma. Gankyrin binds to Mdm2, which results in accelerated ubiquitylation via degradation of p53, and it also plays an important role in cell proliferation. However, little is known about the relationships between p53 levels, cell proliferation, and gankyrin over-expression. Therefore, we investigated the influence of gankyrin on p53 expression and cell proliferation in vitro and in vivo. Methods: We constructed human gankyrin (hgankyrin) expression vectors, pCS2-hgankyrin and pCS2-hgankyrin-EGFP. In order to investigate the influence of gankyrin protein on p53 and Mdm2 in a zebrafish model, we injected hgankyrin-containing expression vector or mock vector as control into zebrafish embryos. RTPCR, northern blot and in-situ hybridization methods were used to measure p53 and Mdm2 expression in hgankyrin-injected embryos and in controls. To observe the effect of gankyrin cell proliferation in vitro, we transfected hGankyrin-containing vector or mock vector into HEK 293 cell line, and trypan blue staining and MTT assay were performed. Following the injection of gankyrin into embryos, we observed cell proliferation in vivo using BrdU immunostaining. Results: We examined levels of p53 that resulted from gankyrin over-expression compared to controls in zebrafish. In vivo results indicated that RNA levels of p53 decreased but those of Mdm2 were not decreased. These results suggest that gankyrin downregulates p53 expression and not Mdm2 expression. In the study of cell proliferation, BrdU-positive cells were predominantly increased in the head and tail regions in hgankyrin-injected zebrafish. Additional in vitro studies using trypan blue staining and MTT assay showed that gankyrin-expressing HEK 293 cells proliferated at a faster rate, indicating that gankyrin promotes cell proliferation. Conclusion: Our results demonstrate that human gankyrin downregulates p53 expression and promotes cell proliferation in
zefrafish. Gankyrin may play an important role in hepatocarcinogenesis via its effects on p53 and cell proliferation.

1262 IN VITRO VALIDATION THAT PHARMACOLOGIC INHIBITION OF FRIZZLED RECEPTORS CAN EXERT ANTI-ONCOGENIC PROPERTIES IN HUMAN CANCEROUS HEPATOCYTES

Sarah Beseme1, Lydie Lefrancois1, Pierre Jalinot2, Christian Trepo1, Ludmila Vitvitski1, Philippe Merle1; 1u871, INSERM, Lyon, France; 2UMR 5161, CNRS-ENS, Lyon, France

Background and Aims: Hepatocellular carcinoma (HCC) is one of the most lethal cancers since therapeutic options are limited. Dysregulation of growth factors and their receptors is central to hepatocarcinogenesis. We previously demonstrated that the Frizzled-7 receptor (FZD7)-mediating the Wnt signaling activates the Wnt/β-catenin pathway and promotes malignancy in hepatitis B virus-related HCC. More recently, we showed that, in addition to FZD7, two other receptors (FZD3 and FZD6) could be activated by WNT ligands in most of human HCCs. Herein we aimed at establishing the proof of principle that pharmacological inhibition of the FZD3/6/7-mediated signalling could exert antitumour activity against HCC cells. Material and Methods: We disposed of human HCC cell lines overexpressing FZD3, 6 and/or 7 (Huh7, SK-Hep1, Focus, PLC/PRE/S, HepG2) and primary normal hepatocytes that do not (Cambrex), as measured by quantitative RT-PCR. We developed a rhodamine-tagged therapeutic peptide (TP) composed of 19 amino-acids containing the Dishevelled-binding domain of FZD3/6/7 linked to a protein transduction domain sequence allowing its penetration within cells, and a control peptide (CP). Antitumor cytotoxicity was assessed by cell counting and MTT test, and apoptosis by Annexin-V staining. Activity on three FZD-dependent pathways was assessed by TOP-Flash reporter gene assay (β-catenin), and western blot with anti-phospho-PKC (PKC) and anti-JNK (JNK). Results: Rhodamine-tagged peptides clearly entered within live hepatocytes (inversed fluorescence microscopy). By contrary to CP, TP exerted apoptosis-mediated cytotoxicity in all HCC cell lines overexpressing FZD3/6/7 while primary hepatocytes survived. When testing specifically Huh7 cells, CP-mediated apoptosis was associated with a substantial decrease in β-catenin and PKC activities, but not in JNK. Ectopic expression of the mutant dominant positive of β-catenin T41A (transient transfection) partially inhibited CP-induced apoptosis, and HepG2 cells (β-catenin mutants) were less sensitive to TP. Conclusions and perspectives: We have brought the proof of principle that in vitro pharmacological inhibition of some of the FZD receptors could engender antitumor effect in cancerous hepatocytes. This effect is mediated via at least inhibition of β-catenin, and maybe through PKC pathway repression too. These data underlined that FZD could be a very attractive target for therapeutic intervention in HCC.

1263 HYPOXIA INDUCED GENE EXPRESSION SIGNATURE IN NORMAL HEPATOCYTES AND HUMAN HEPATOCELLULAR CARCINOMA

Salvador Naranjo-Suarez, Valentina M. Factor, Cedric Coulourn, Snorri S. Thororgeirsson; NCI, NIH, Bethesda, MD

Hepatocellular carcinoma (HCC) is the most common liver malignancy and among the five leading causes of cancer death in the world. HCC treatment options remain limited, and surgical resection is considered the only curative treatment. However, patients who undergo surgery, suffer frequent and often early recurrences. Also standard clinical pathological classification of HCC has limited usefulness for predicting the outcome of treatment. Therefore, molecular characterization of HCC into homogenous subtypes may provide an important step in improving the treatment options and success. HCC is considered a hypervascular tumor, and expression of the hypoxia inducible factor (HIF) and its target genes has been reported to be associated with a poor prognosis phenotype. Using a comparative genomics approach, we have characterized the hypoxic gene expression profile in freshly isolated mouse hepatocytes, with the aim of using this profile to explore the importance of the hypoxic response in HCC. Culture of mouse hepatocytes under hypoxic conditions over 24 hours revealed more than 1800 significant (p<0.001) regulated genes. In the first 12 hours the most important response to the hypoxic conditions is the upregulation of genes involved in angiogenesis, blood vessel formation and blood coagulation, while the transition to an anaerobic metabolism seems to be the most important response after 24 hours. Genes that showed at least 2 fold expression difference between hypoxic and normoxic conditions were selected to define the hypoxia gene expression signature. 504 orthologous genes derived from the hypoxic signature were used to perform hierarchical cluster analysis of 139 human HCC. As a result, two subsets of genes were identified. One subset of 104 genes implicated in cell cycle and apoptosis regulation (e.g. Gadd45a, Cdk4, Map4k4, Dusp1, Csk2), blood coagulation (e.g. Plg, F2, F9, F13b, Hc, Agt, Serpins1, Serpinf1) and immune response (e.g. C1r, C8a, C8b, C8g, C9, Rarres2) among other functions, was able to predict HCC with a good prognosis. On the other hand, a subset of 62 genes, some of them involved in cell cycle progression (e.g. Cdk6, Ches1, Ccn1, Nfgb), apoptosis regulation (e.g. Bcl6b, Pik3r1) and angiogenesis (e.g. Vegf, Id3), was able to predict HCC with a poor prognosis. Interestingly, among these 62 genes, we identified some that have already been found to predict poor prognosis in other human cancers (Chin et al. PLoS Medicine. 2006 Mar; 3[3]). Further studies are aimed at characterizing the mechanisms by which hypoxic conditions regulate these 2 sets of genes.

1264 CHROMATIN-BASED ANALYSIS OF THE IFNα TRANSCRIPTOME REVEALS FUNCTIONALLY DISTINCT SUBSETS OF STAT2 DIRECT TARGET GENES

Barbara Testoni1,2, Christine Voellenke2, Giovanni Blandino2, Massimo Levrero1,2; 1Dept. Internal Medicine, University of Rome La Sapienza, Rome, Italy; 2Rome Oncogenomic Center (ROC), Rome, Italy

Background/Purpose: Virus and host factors associated with responsiveness to IFN-based anti-HCV therapies have been identified but the underlying molecular mechanisms are still
unknown. Recently, the up-regulation of a specific set of IFN-responsive genes has been shown to predict non response to exogenous therapy. Aiming to understand the molecular mechanisms that differentiate responder and non-responder CHC patients we have developed innovative tools for systematic investigation of target gene regulation in response to IFNα and the classification of IFNα/STAT2 direct target genes into functionally homogeneous subsets according to transcription rules. Methods: We have used a Chip-on-chips approach, that couples chromatin immunoprecipitation (Chip) with custom-made oligonucleotides microarrays, to analyze IFNα/Stat2 direct target genes regulation at the chromatin level. Chip analysis were performed with anti-AcH3, anti-SS-PolII, anti-STAT2 and anti-P-STAT2 abs. Results: By in silico analysis and literature survey, 113 IFNα/β, but not IFNγ, direct target genes (i.e. modulated by IFNα/β and containing >80% conserved ISRE sequences in their promoter or first intron) have been selected. 34 genes were already confirmed by Chip and 79 genes were out of >300 genes modulated in previously published microarrays analysis. To build-up the STAT2 dedicated microchip slide 3 different 50mer oligos for each of the 113 target gene were designed (upstream promoter, proximal promoter, downstream of the TSS), spotted in triplicate and the resulting array printed 4 times on the same slide for a total of 4068 spots. Gene ontology analysis of the 113 selected genes revealed that the spectrum of direct IFNα/β target genes is far more varied than expected. Chip and Chip-on-chip analysis have revealed different classes of IFNα/β target genes in terms of STAT2 and PolII promoter occupancy before IFNα/β treatment and phospho-STAT2 recruitment (early vs late) after IFN stimulation. In particular, STAT2 is already bound to more than 50% out of the 113 direct target genes analyzed before IFN treatment, both in the group of genes upregulated and/or downregulated. Moreover, 37 new direct IFNα/β target genes have been identified, including Dnp73 (a p53/p73 antagonist that blocks apoptosis, induces cell proliferation and is upregulated in human HCCs), HIF1 (involved in hypoxia response) and the transcriptional repressor HDAC10. Conclusion: The Chip-on-chip reagents and approach we have developed represent a powerful tool to characterize the IFNα/Stat2 transcriptome in the liver in vivo in the perspective to develop to predict and modulate IFNa resistance in hepatitis C patients.

COMPREHENSIVE GENE EXPRESSION ANALYSIS IN HEPATOCELLULAR CARCINOMA (HCC) BY NEWLY DEVELOPED 5'-END SAGE METHOD AND IDENTIFICATION OF NOVEL UP-REGULATED INTRONIC TRANSCRIPT

Yuji Hodo1,2, Shin-ichi Hashimoto2, Shungo Deshimaru3, Masao Honda1, Taro Yamashita1, Teruyuki Ueda1, Kouji Matsushima2, Shuichi Kaneko1

Introduction: Gene profiling is a powerful technique for understanding the genomic and molecular alterations related to carcinogenesis. Gene expression analysis of hepatocellular carcinoma (HCC) has been performed extensively; however, most gene expression data has been derived from the 3’-end region of mRNA. Recent advances in molecular biology have revealed diverse transcriptional start sites (TSS) and the biological significance of intron initiated RNA. We recently developed a 5’-end SAGE method that combines the oligo-cap and original SAGE methods and quantitatively provides comprehensive tag sequences transcribed from the TSS (Nature biotechnology). In this study, we applied this 5’-end SAGE method to gene expression analysis in hepatocellular carcinoma (HCC) for the first time. Materials and Methods: Samples were obtained from a patient with HCC who had undergone surgical hepatic resection. Serological tests of HBs antigen and HCV antibody were negative. Tumor (T) and non-tumor (NT) tissue were separately obtained from either tumorous or non-tumor parts of the resected tissue. We also prepared 5 normal liver (NL) tissue samples from 5 patients who had undergone surgical hepatic resection because of metastatic liver cancer. Another 4 normal liver tissue samples, 42 HCC tissue samples and 42 NT tissue samples were used for real-time detection (RTD)-PCR. Results: We analyzed about 225,000 tags in 3 libraries and mapped them to the human genome. Gene profiles were made based on positional information of ref_seq genes. A total of 254 genes were up-regulated by more than 5-fold and 172 genes were down-regulated by more than 5-fold in the T library when compared with to NL library. The gene expression profiles agreed with previous reports. However, we also identified 5’-end SAGE tags corresponding to intronic region in 2179 genes. These genes were related to signal transduction, transport, energy pathways, and protein metabolism and so on. We successfully cloned full transcripts that initiated from the intronic region. Interestingly, we found that one of these intronic transcripts was significantly up-regulated in 43 T tissues when compared with NT tissues, as determined by RTD-PCR. Furthermore, expression of the overlapping defined mRNAs was significantly repressed in the 43 T tissues, thus suggesting repressive regulation of intronic RNA for overlapping defined mRNAs. Conclusion: We obtained comprehensive gene expression profiles of the 5’-end regions of mRNA in HCC. Identification and expression analysis of novel transcripts is useful for further elucidation of HCC pathogenesis, and detection of novel diagnostic and therapeutic targets.

HYDRODYNAMICS-BASED INJECTION OF A SHORT HAIRPIN RNA-PRODUCING VECTOR TARGETING C-JUN IN RAT LIVERS

Kazuyuki Hanajiri1, Hiroshi Mitsui1, Toshiyuki Maruyama1, Naoaki Hashimoto2, Haruki Yamada3, Masao Omat1; 1Gastroenterology, The University of Tokyo, Tokyo, Japan; 2Gastroenterology, Tokyo Teishin Hospital, Tokyo, Japan; 3Gastroenterology, Social Insurance Central General Hospital, Tokyo, Japan

Background: RNA interference is a recently discovered mechanism for silencing gene expression. Hydrodynamics-based injection of si RNA into mice has been a useful model both for investigating functions of genes and for treating pathological conditions. However, reports of gene silencing in rats have been very scarce. In this study, we inhibited expression of c-Jun in rat livers by a hydrodynamics-based method and examined the function in stimulated conditions. Methods: A vector producing short hairpin RNA specific for rat c-Jun transcript under CMV promoter was constructed. Male Wistar rats weighing 100-120 g were injected with several different volume of Ringer solution containing either control- or c-Jun silencing vector via tail veins within 30 seconds. Large vessels around the liver were inspected by ultrasound images. One hour after...
1267 CLINICOPATHOLOGICAL SIGNIFICANCE OF EZH2 AND BMI1 EXPRESSION IN PATIENTS WITH HEPATOCELLULAR CARCINOMA

Yutaka Yonemitsu1, Fumio Imaizeki1, Nagai Yuichiro2, Kenichi Fukai1, Makoto Arai1, kaiyu zhang1, Keiichi Fujiwara1, Osamu Yasukawa1, Toshiyuki Maruyama, Naoaki Hashimoto, Haruki Yamada, Masao Omata

Introduction/Aims: EZH2, a member of Polycomb repressive complex 2 and BMI1, a member of Polycomb repressive complex 1, play a crucial role in the regulation of embryonic development and have been associated with the regulation of cell cycle. Recently, several studies have shown that EZH2 is highly expressed in aggressive tumors, including breast and prostate cancer, and BMI1 is highly expressed in lymphomas. BMI1 represses the expression of P16INK4a and P19ARF tumor suppressor genes leading to carcinogenesis. We thus analysed EZH2 and BMI1 expression immunohistochemically, and correlated its expression status with various clinicopathological parameters in patients with hepatocellular carcinoma (HCC).

Materials and Methods: The expression of EZH2 and BMI1 was examined in surgically resected 85 HCC nodules and corresponding non-tumor tissues from 75 patients. The tissue sections were immunohistochemically stained with a primary antibody against EZH2 (Zymed) and BMI1 (Upstate), respectively. Clinicopathological factors examined were as follows: age, sex, liver function tests (levels of total bilirubin, albumin, AFP, PIVKA2 and platelet count, and so on), and tumor factors (tumor size, tumor number, invasion to portal vein, hepatic vein and bile duct and so on). Cumulative survival and recurrence rates were analyzed by Kaplan-Meier method. Results: EZH2 and BMI1 were exclusively detected as nuclear staining of HCC cells and non-tumor hepatocytes. The expression of EZH2 was found in 46/75 (61.3%) and 4/75 (5.3%) of tumor and non-tumor tissues, respectively. Both of EZH2 and BMI1 were stained in 43/75 (57%) tumor tissues and neither of them were stained in 21/75 (28%). The correlation between expression of EZH2 and various clinicopathological factors showed higher albumin level associated with the expression of EZH2 (P=0.01). The correlation between expression of BMI1 and various clinicopathological factors showed greater tumor numbers associated with the expression of BMI1 (P=0.03). There was no difference of cumulative survival rates between patients positive and negative for EZH2 staining, and between patients positive and negative for BMI1 staining. There were higher cumulative recurrent rates in patients positive for EZH2 or BMI1 staining than those negative for EZH2 or BMI1 staining (P=0.038 and P=0.048 respectively). Conclusion: The expression of EZH2 and BMI1 were very frequent and specific in tumor tissues of HCC, thus can be a close association with the development of HCC and might be associated with higher cumulative recurrent rate.

1268 RNA INTERFERENCE MEDIATED SILENCING OF EGFR IN REGENERATING RAT LIVER FOLLOWING A PARTIAL HEPATECTOMY

Shirish Paranjpe, William Bowen, George Michalopoulos; Pathology, University of Pittsburgh, Pittsburgh, PA

Liver regeneration after partial hepatectomy (PHx) is an extremely complex process requiring interaction and cooperation of many growth factors and cytokines and crosstalk between multiple pathways. Along with HGF-met, the EGFR signaling pathway is also activated within 60 minutes after a PHx. EGFR phosphorylation also increases over basal levels by 60 minutes after a PHx; exactly paralleling activation of c-met. Cross talk between these two pathways has been documented and integration of these two pathways may be required for regeneration to proceed efficiently. We therefore decided to use shRNA to knock out EGFR expression in regenerating normal rat liver by following a protocol we recently published (Hepatology, 45:1471-1477, 2007) The EGFR family contains four members; Erbb-1, Erbb-2, Erbb-3 and Erbb-4. Erbb-3 is not expressed in liver while Erbb-2 is expressed only in embryonic liver and not in adult liver. Only Erbb-3 is expressed in the adult liver but has no intrinsic kinase activity and relies on Erbb-1 for activity. The four Erbb receptors recognize 11 different but structurally related growth factors that mediate diverse process like development, cell proliferation, and cell survival. Two EGFR rat specific short hairpin sequences were designed and cloned under the control of human H1 promoter. JM1 cells were transfected with the plasmids singly or in combination and screened for their ability to suppress EGFR expression. Stable transfecants expressing GFP were isolated in presence of zeocin. Levels of EGFR mRNA were estimated by both semi quantitative and real time PCR. Suppression of EGFR mRNA was evident. The plasmids were then injected in rats by following protocols reported earlier. Significant suppression of EGFR mRNA by day one post PHx was observed following two shRNA injection. How ever in contrast to the effects observed following c-met silencing, no suppression of mitosis was evident, probably indicating that although the c-met and EGFR pathways are similar, the contributions made by c-met are unique which are not compensated by EGFR or other cytokines related to liver regeneration. We are currently investigating the effects of EGFR

RNAi THERAPEUTICS FOR THE TREATMENT OF LIVER DISEASES
Akin Akinc1, Daniel Anderson2, Birgit Bramlage2, David Bumcro1, J. Robert Dorkin1, Kevin Fitzgerald1, Maria Frank-Kamenetsky1, Michael Goldberg3, Jens Harborth1, Jay D. Horton4, K. Narayanannair Jayaprakash1, Muthusamy Jayaraman1, Matthias John1, Kallanithattil Rajeev1, Victor Kotelianski1, Robert Langer1, Muthiah Manoharan1, Lubomir Nechev1, June Qin1, Timothy Racie1, Ingo Roh1, Dinah Sah1, Jürgen Soutschek2, Hans-Peter Vornlocher2, Tracy Zimmermann1, Andreas Zumbuehl1, George Michalopoulos1

Successful delivery of small interfering RNAs (siRNAs) in vivo, using clinically relevant modes of administration, is critical for the advancement of RNA interference (RNAi) therapeutics. Here we describe a new class of lipid-like delivery molecules, which we term lipidoids, as delivery agents for RNAi therapeutics. Chemical methods were developed to allow the rapid synthesis of a large library of over 1,200 structurally diverse lipidoids. From this library, lipidoids were identified that facilitate high levels of specific silencing of endogenous gene transcripts. Using these materials, we have developed a novel liposomal formulation optimized for delivery of systemically-administered siRNA to the liver. Numerous endogenous liver genes have been successfully silenced employing this formulation in both rodent and nonhuman primate models. Specifically, we describe the potent down-modulation of two non-druggable disease targets, apolipoprotein B (apoB) and propionate convertase subtilisin kexin 9 (PCSK9). In nonhuman primates, a single injection of liposomal siRNA resulted in up to 85% silencing of apoB mRNA expression in the liver 48 h after administration. PCSK9 down-modulation has been demonstrated in mouse, humanized mouse, rat, and nonhuman primate models. Silencing of PCSK9 resulted in significant lowering of cholesterol (20-40%) in all animal models tested with 60% lowering of total cholesterol in the rat model. These findings demonstrate clinically relevant RNAi-mediated gene silencing, thus supporting the potential of RNAi therapeutics as a new class of drug for liver diseases.

INHIBITION OF TNF ALPHA STIMULATION BY PRE-TREATING HUMAN HEPATOCYTES WITH STAUROSPORINE AND LY294002 ON INTRINSIC APOPTOSIS PATHWAYS
Andromachi Kotsafi1, Anna Granato4, Maria Teresa Vilei2, Chiara Carlotto1, Maurizio Muraca2, Marina Bartolami1; 1Dept of Surgical and Gastroenterological Sciences, University of Padua, Padova, Italy; 2Internal Medicine, University of Padua, Padova, Italy; 3Laboratory Medicine, Hospital Bambin Gesù, Roma, Italy; 4Laboratory of Histopathology, Istituto Zooprofilattico Sperimentale delle Venezie, Padova, Italy

Introduction. In acute and chronic liver disease, hepatocytes are exposed to higher quantities of cytokines [TNF-alpha (tumor necrosis factor alpha), IL-1-beta (interleukin 1 beta), INF-gamma (interferon gamma)], oxidative stress and bile acids. Though hepatocytes have an enormous capacity to defend themselves against these agents, excessive exposure results in cell death. Apoptosis deregulation plays a pivotal part in the development of numerous liver diseases. The binding of death receptors expressed on the hepatocyte’s surface to their ligands can activate closely-linked extrinsic and intrinsic pathways. To characterize the variability of the apoptotic process in healthy human hepatocyte cultures, the aims of this study are: 1) to determine whether the main proinflammatory TNF-alpha cytokines abounding in inflammatory processes related to liver injury can regulate and modulate Fas/FasL mRNA expression; 2) to assess the effects of hepatocyte pre-treatment with staurosporine (STS), a potent protein tyrosine/serine kinase, and LY294002, a synthetic inhibitor of PI3K (phosphoinositide 3-kinase), on the intrinsic (Bcl-2, Bax, Bad, NF-kB) and extrinsic (IL-1beta, TGF-beta, Fas/FasL) apoptotic pathways. Materials. Human hepatocytes were separated from livers rejected for transplantation, 3 X 106 and viable hepatocytes were suspended in six-well plates coated with acellular liver matrix and stimulated in medium with no fetal calf serum using different doses of TNF-alpha, STS and LY294002 for different times (4, 8, 12, 24 and 48 h). mRNA levels were quantified by real-time PCR. Results. Up to 48 h, TNF-alpha induced a significant increase in IL-1beta, Bcl-2 and NF-kB mRNA transcripts in human hepatocytes (p<0.0001, p=0.0029, p=0.0035 by Kruskal-Wallis, respectively), whereas Bax and Bad mRNA levels were inhibited without however reach a statistical significance. No differences in Fas mRNAs were observed while FasL overexpression was observed only after 12h of stimulation with TNF-alpha (p=0.05). Pretreating hepatocytes with LY294002 and staurosporine blocked the effects of TNF-alpha on Bcl-2 and NF-kB mRNA transcripts, while inducing the overexpression of TGF-beta. Conclusions. TNF-alpha is a proinflammatory cytokine constantly found in the micro-environment in acute and chronic disease that activates both extrinsic (IL-1beta, Fas/FasL) and TGF-beta (mRNAs overexpression) and the intrinsic (NF-kB, Bcl-2) apoptosis processes. Pretreating hepatocytes with PI3K inhibitors activates the intrinsic pro-apoptotic pathways, increasing Bax and Bad mRNAs. Our results shed light on how extracellular mediators may be involved in controlling the survival and death of primary human hepatocytes.

1271 MODULATION OF STEMNESS IN DYSFUNCTIONAL PROGENITOR/STEM CELLS ALTERS CANCER FORMATION IN THE LIVER

Choohee Yun1, Michael J. Pishvaian1, Yi Tang1, Krit Kitisin1, Eugene A. Volpe1, Jonathan S. Mendelson1, Wilma Jagoonoori1, Culing Li2, Chu-Xia Deng3, Susette Mueller1, Habibom Ressom1, Asif Rashid1, Anton N. Sidawy2, Stephen R. Evans1, Kirti Shetty1, Michael Zasloff1, Bibhuti Mishra1, E. P. Reddy3, Lynt B. Johnson1, Lopa Mishra1,2, 1Georgetown University, Washington, DC; 2Veterans Affairs Medical Center, Washington, DC; 3Temple University, Philadelphia, PA; 4MD Anderson Cancer Center, Houston, TX; 5National Institutes of Health, Bethesda, MD

It is thought that at least 40% of hepatocellular cancer (HCC) are clonal and arise from dysfunctional progenitor/stem cells. Functional mechanisms involved in generation and renewal of these “cancer stem cells”, such as those of liver, remain poorly defined and are vital for the development of new targeted therapeutics for this poor prognosis cancer. We therefore chose to investigate pathways involved both in renewal and maintenance of stem cells and tumor suppression such as the TGF-β signaling pathway. Signaling molecules of the TGF-β pathway such as Smad2, Smad3 and an adaptor protein, ELF, are known to play pivotal roles in liver development and HCC suppression. Lethal liver hypoplasia was observed in elf/- and smad2+/−/smad3+/−/elf+/− mice develop frequent and spontaneous HCC by 12-15 months of age. Through studies in human living donor transplants our group identified a small population of stem cells in fully regenerated human liver that express all TGF-β markers which are lost in human HCC. Aims: 1. To identify functional pathways which are involved in renewal of TGF-β regulated liver cancer stem cells 2. To modulate these pathways and decrease HCC formation. Methods and Results: 1. Broad microarray proteomic analysis and immunohistochemical staining (IHC) reveal marked activation of IL-6/Stat3 signaling as well as cell cycle regulators such as CDK4 in HCC tissues from elf−/− mice. 2. Genetic abrogation of IL-6/Stat3 signaling in elf−/−/itih4−/− mice dramatically decreases the incidence as well as the size of HCC when compared to elf+/− mice. 3. Abrogation of CDK4 in elf−/−/CDK4−/− mice also reduces HCC formation. 4. Immunoprecipitation demonstrates the interaction between CDK4 and ELF which leads to phosphorylation of ELF. 5. In vitro biochemical studies shows that restoration of normal ELF expression significantly increases the percentage of cells in G1 arrest, decreases the expression of CDK4, and restores TGF-β target gene activation. Conclusions: Genetic studies demonstrate a link between IL-6/Stat3 pathway, a major stem cell signaling pathway, and TGF-β signaling pathway in the modulation of HCC which derive from altered TGF-β phenotypes. Also interaction of CDK4, a major regulator of cell cycle progression, and ELF suggests that liver cancer stem cells have dysregulated cell cycles with a short G1/S phase when ELF is disrupted. These two signaling pathways are shown to be involved in HCC formation from altered TGF-β phenotypes thereby presenting important therapeutic targets in treating HCC.

1272 BETA-CATENIN IS INDISPENSABLE FOR LIVER DEVELOPMENT AND SURVIVAL

Xinping Tan1, Sattarshan P. Monga1,2, 1Pathology, University of Pittsburgh, SOM, Pittsburgh, PA; 2Medicine, University of Pittsburgh, SOM, Pittsburgh, PA

β-Catenin, the central component of the canonical Wnt pathway, plays important roles in the processes of liver regeneration, growth and cancer. Previously, we have identified temporal expression of β-catenin during liver development. Here we characterize the hepatic phenotype only, resulting from the successful deletion of β-catenin in the developing hepateoblasts during liver development utilizing Foxa3-Cre transgenic and floxed-β-catenin (Ex2-6) transgenic mice. β-Catenin loss in developing livers resulted in significantly underdeveloped livers after embryonic day 12 (E12) with lethality occurring at around E17 stages. Histology revealed an overall deficient hepatocyte compartment along with remnant hepatocytes possessing an immature phenotype as indicated by high nuclear to cytoplasmic ratio, poor polarity and absent glycogen. The decrease in the hepatocyte numbers were due to a) increased cell death due to oxidative stress and apoptosis, and b) diminished expansion secondary to impaired proliferation. A concomitant paucity of primitive bile ducts was also evident. While the stem cell assays demonstrated no intrinsic defect in hepatopoiesis, distorted hepatic architecture and deficient hepatocyte compartment resulted in a defect in the endothelial cell organization and homeostasis, leading to impaired hepatic blood flow, fetal pallor and lethality. Conclusion. β-Catenin regulates multiple, critical events during the process of hepatic morphogenesis including an important role in hepatoblast maturation, expansion and survival and its hepatic disruption is indispensable to survival.

Disclosures:

Hepatocellular cancer (HCC) remains a poor prognosis cancer and a significant number of cases are thought to arise from dysfunctional stem/progenitor cells. In adult humans, these liver stem/progenitor cells are immature epithelial cells found residing in the canals of Hering. Long term label retention of these multi-potent cells with high proliferative potential has been one approach towards identifying them in the gut epithelium. However, to date, identification of such liver stem/progenitor cell populations has remained elusive. Recent studies have shown that TGF-β signaling members TGF-β receptor type II (TBRII), Smad2, Smad4 and Smad-adaptor ELF, α-spectrin, play crucial roles in liver development and function as tumor suppress-
sors in hepatocarcinogenesis. Elf-/- and smad2+-/-smad3+-/-mutant mice are embryonic lethal from hepatic hypoplasia. In addition, as many as 40% of elf-/- mice (17/40) spontaneously develop HCCs. Aims: 1. To identify TGF-β-regulated liver stem/progenitor cell population. 2. To investigate whether the TGF-β phenotype is altered in human HCCs. Methods and Results: 1. Immunohistochemical labeling (IHC) was performed in post living donor liver transplanted tissues taken from 5 different recipients at 3 months after surgery. We identified 2-3 cells out of 30,000-50,000 cells which express embryonic stem cell markers Oct4 and Nanog localized around portal tract areas. These cells are also stained positively for ELF and TBRII. 2. Confocal triple labeling confirms co-localization of Oct4 and ELF in these cells along with a proliferative marker p-Histone and another important embryonic stem cell marker Stat3. 3. The Oct4+- cells express both cholangiocyte cell lineage marker CK19 and hepatocytic cell lineage marker albumin. 4. IHC labeling of 10 human HCC specimens reveals a distinct cluster of Oct4+- cells. Interestingly, these regions no longer expressed TBRII and ELF in 9 out of 10 samples. Conclusions: Genetic studies through elf knockout mice reveal a functional role of the TGF-β signaling pathway in HCC suppression and liver development. Prominent expression of TGF-β signaling proteins observed in the Oct4+/-Nanog+/-Stat3+ cells indicates that these cells are under TGF-β regulation and could represent a TGF-β-regulated stem/progenitor cell population. The identification of Oct4+ cells in human HCC specimens coupled with absence of TGF-β proteins in those areas suggests that the liver stem/progenitor cells with altered TGF-β phenotype could develop into cancer stem/progenitor cells. Understanding regulation of such “cancer stem cells” could provide novel therapeutic approaches in treating this cancer.

1274 EXPRESSION OF NEIGHBOR OF PUNC E11 (NOPE) DURING MURINE LIVER DEVELOPMENT

Dirk Nierhoff, Sigrid Schulte, Jens Marquardt, Gisela Holz, Tobias Goeser; Department of Gastroenterology and Hepatology, University of Cologne, Cologne, Germany

We have previously shown that murine fetal liver epithelial cells at embryonic day (ED) 12.5 are a homogeneous population of hepatoblasts that can be purified using the specific surface markers E-cadherin, Liv2 or Dlk. In a DNA microarray analysis comparing purified hepatoblasts isolated from ED 13.5 mouse fetal liver with adult liver (AL), we identified the membrane protein Neighbor of Punc E11 (Nope) to be significantly higher expressed in hepatoblasts than in AL. In the current project, we focused on the differential expression of Nope as a potential marker for bipotential hepatoblasts during liver development. Methods: We isolated livers at different stages of development (fetal, postnatal and adult livers) starting at ED 11.5. RNA and protein fractions were extracted and quantitative RT-PCR and Western blot studies were performed to quantify the expression level of Nope with Gapdh and β-Actin as internal controls. Immunohistochemistry and confocal microscopy were performed on cryosections. Stainings for Nope were combined with stainings for epithelial-specific markers (pancytokeratin, E-cadherin), markers of early hepatoblasts (Afp, Liv2) and hepatocytic (albumin) or biliary marker proteins (CK 19) at different stages of liver development. Results: Quantitative RT-PCR showed that Nope is highly expressed in fetal liver starting at ED 11.5, but is rapidly down regulated postnatally until 2 weeks after birth and no longer detectable in AL. Western Blot studies confirmed the expression of Nope in the membrane fraction of liver extracts until 2 days after birth. Immunohistochemistry demonstrated the specific coexpression of Nope with epithelial-specific markers as well as with markers of bipotential hepatoblasts in early fetal liver development. After commitment of hepatoblasts to cholangiocyte/hepatocytic differentiation, Nope was continuously expressed on both cell types until 2 days after birth as identified by co stainings with hepatocytic and bilary markers. Nope was not detected above background level in AL. Conclusion: Nope is a membrane protein specifically expressed by epithelial cells within the liver at all stages of fetal liver development and is rapidly down regulated after birth. While Nope is initially expressed on the surface of bipotential hepatoblasts, it continues to be expressed on fetal hepatocytes and cholangiocytes until 2 days after birth and is no longer detectable in AL. Further studies will focus on the potential use of Nope as a surface marker for stem/progenitor cells in the adult liver.

1275 SELECTIVE PROLIFERATION OF HUMAN HEPATOCYTE PROGENITOR CELLS IN COMBINATION WITH HYALURONIC ACID AND SERUM-FREE MEDIUM

Toshihiro Mitaka1, Kazunori Sasaki2, Junko Kan1, Qijie Chen1, Hidekazu Ooe1, Hideki Oshima2, Toru Mizuguchi2, Koichi Hirata2, 1Pathophysiology, Sapporo Medical University Cancer Research Institute, Sapporo, Japan; 2Surgery, Sapporo Medical University, Sapporo, Japan

Background&Aim: Small hepatocytes (SHs) were first identified as a subpopulation of rat hepatocytes that had high replication potential in culture. Therefore, SHs may be ‘committed progenitor cells’ that can further differentiate into mature hepatocytes (MHs). We have recently reported that CD44, one of the hyaluronan receptors, is a specific marker for rat SHs and that rat SHs can selectively proliferate on a hyaluronic acid (HA)-coated dish in a serum-free medium. The aim of the present study is to isolate human SHs from normal adult livers and to culture them in serum-free medium for a long term. Methods: Normal liver tissues were obtained from resected specimens from patients who underwent hepatic resections at Sapporo Medical University under informed consent and with the approval of the Sapporo Medical University Ethics Committee. All tissues were obtained from the patients who had never had any hepatitis viral infections. Hepatic cells were isolated and then plated on HA-coated dishes. The cells were cultured in serum-free DMEM/F12 medium supplemented with nicotinamide, EGF, HGF, ITS, and Dexamethasone. Immunocytochemistry, ELISA, and RT-PCR were carried out. Results: When the isolated cells were plated on HA-coated dishes, some small-sized hepatocytes proliferated to form colonies. Many colonies continued growing for more than 3 weeks. The average number of cells in a colony was 38.6±18.0 at day 14, 79.0±54.0 at day 14, and 101.5±115.7 at day 21. About 0.04% of plated cells could form an SH colony. Immunocytochemistry showed that the cells were positive for albumin, transferrin, CK8 and CD44. Most cells showed CK19 positivity. The results of RT-PCR showed that colony-forming cells expressed not only albumin, transferrin, α1AT, fibrinogen, and glutamin synthetase but also liver-enriched transcription factors such as HNF3α, HNF4α,
C/EBPα, and C/EBPβ. In addition, cytochrome P450 isozymes such as 2A6, 2B6, 2C9, 2D6, 2E1, 3A4, and 3A5 were also expressed. Furthermore, the cells expressed Thy1.1, EpCAM, and AFP, which are expressed in hepatic stem cells, as well as CD44 and D6.1A, which are SH markers. Albumin was secreted into culture medium. The results indicate that human hepatocyte progenitor cells may be isolated and can grow on HA-coated dishes cultured in a serum-free medium. The human cells show characteristics similar to rat SHs. Conclusion: Human SHs may be a useful source for pharmacological examinations and cell transplantation.

1276 REGULATION OF HEPATIC LINEAGE ADVANCEMENT IN HESC THROUGH A MESO-ENDODERMAL INTERMEDIATE RECAPITULATES FETAL STAGE-SPECIFIC PROCESSES

Sriram Bandi, Brigid Joseph, Kang Cheng, Sanjeev Gupta; Marian Bessin Liver Research Center, Albert Einstein College of Medicine, Bronx, NY
To advance applications of stem cells, mechanisms driving cell differentiation into specific lineages need to be defined. As one way to understand lineage advancement mechanisms is to study stage-specific processes, differentiation of human embryonic stem cells (hESC) along hepatic lineages should benefit from analysis of lineage advancement in the context of organ development. In freshly isolated fetal human epithelial cells from the liver or pancreas at 20-24 week gestation, we demonstrated multilineage gene expression, including presence of epithelial, mesenchymal and stem cell genes. These cells underwent genetic reprogramming in culture suggesting reversion to more primitive meso-endodermal stages. To determine whether such a stage was recapitulated in hESC-derived epithelial lineages, we studied mesenchymal stem cells obtained from the WiCell H1 cell line, where spontaneously originating cells during fetal liver development in vivo and during hESC differentiation in vitro. The efficacy of hESC-derived cells in liver failure will eventually help advance clinical applications.

1277 ANALYSIS OF DIFFERENTIATION OF HEPATIC PROGENITOR CELLS DERIVED FROM SEVERELY INJURED RAT LIVERS

Junko Kon1, Kazunori Sasaki2, Hideki Oshima2, Toshihiro Mitaka1; 1Pathophysiology, Sapporo Medical University, Sapporo, Japan; 2Surgery, Sapporo Medical University, Sapporo, Japan
Background & Aim: Small hepatocytes (SHs) are a subpopulation of hepatocytes that have high growth potential in culture. SHs can clonally proliferate to form colonies and differentiate into mature hepatocytes (MHs) by interacting with hepatic nonparenchymal cells (NPCs). Thus, we consider that SHs may be hepatic progenitor cells that can further differentiate into MHs. Recently, we identified CD44 as a specific gene that expressed in proliferating SHs. On the other hand, oval cells is known as hepatic stem cells that appear in severely injured livers. The aim of the present study is to analyze the mechanism of differentiation and the fate of hepatic stem/progenitor cells in vivo and in vitro. Methods: Male F344 (DPPIV+) rats were treated with 75 mg/100g body weight D-galactosamine (GalN) and frozen section were made from the liver for immunohistochemistry. Thy1+ or CD44+cells were sorted by using MACS. The sorted cells were cultured, transplanted, or used for RTPCR. Female DPPIV- rats were treated twice with 30 mg/100g body weight retorsine following 2/3PH and used for cell transplantation. Results: Immunohistochemistry showed that Thy1+ oval cells were observed in the livers at day 2 after GalN-treatment (GalND2) and day 3 after GalN-treatment (GalND3). Some Thy1+-cells in the livers of GalND3 also showed CD44-positivity. CD44+ hepatocytes were also observed in the perportal area of liver lobules at day 4 after GalN-treatment (GalND4). The sorted CD44+-cells from the liver of GalND4 could proliferate and form large CD44+colonies. Although Thy1+-cells from GalND2 formed few colonies, those from GalND3 effectively formed CD44+colonies. RT-PCR revealed that Thy1+-cells from GalND3 expressed CD44, Dlk-1, C/EBPα. In addition, they were cultured between collagen gels in the medium without dexamethasone, many Thy1+-cells from GalND3 could differentiate into biliary duct cells, whereas most Thy1+-cells from GalND2 could not. At 30 days after cell transplantation the number and area of DPPIV+ cells in the livers were shown in Table 1. From these results, Thy1+/CD44- cells could not form SH colonies and Thy1+/CD44+ could form SH colonies. Therefore, Thy1+/CD44+ cells may differentiate into Thy1-/CD44- SHs, and then the SHs may differentiate to Thy1-/CD44- MHs. Conclusion: A part of oval cells may differentiate into hepatocytes via SHs or into BECs.

1278 INDUCTION OF PANCREATIC BETA-CELL PHENOTYPE IN HEPATIC PROGENITOR CELLS (HPC) ISOLATED FROM ADULT DIABETIC MICE

Ran Tur-Kaspa1,2, M. Vorobeychik2,3, R. Zemel2, K. Bloch3, L. Bachmatov2, P. Vardi3,1 Medicine D & the Liver Institute, Rabin Medical Center -Beilinson Hospital, Petach-Tikva, Israel; 2Molecular Hepatology Lab., Felsenstein Medical Research Center, Tel-Aviv University, Rabin Medical Center, Petach-Tikva, Israel; 3Diabetes Research Lab., Felsenstein Medical Research Center, Tel-Aviv University, Rabin Medical Center, Petach-Tikva, Israel

Various studies have shown that liver cells constitute a promising cell source for induction of insulin production and secretion following different cell procedures. However, the potential of diabetic-derived adult stem cells to induce pancreatic beta cell phenotype has not been elucidated. Here we present our in-vitro study on induction of beta cell phenotype in hepatic progenitor cells (HPC) obtained from intact and diabetic mice. Our hypothesis was that hepatic progenitors, isolated from diabetic liver may be more committed to differentiate into beta cell phenotype, than cells derived from non-diabetic animals. HPC were obtained from livers of intact, control HPC (cHPC) and STZ-induced diabetic male mice (dHPC) 12 weeks old, undergoing hypoxic conditions. Cell expansion was performed by exposure of cells to conditioning culture medium able to induce a high number of HPC (1X10^7/mouse). Differentiation of HPC toward insulin producing cells was shown by RT-PCR and immunohistochemical analysis using a series of different markers including HNF-3β, PDX-1, NGN-3, insulin-1 and insulin-2. Insulin production in differentiated cells was evident by immunocytochemistry, as well as by ELISA determination of insulin content and secretion. Following hypoxic selection a higher expression level of insulin producing cells differentiation markers, such as HNF-3β and PDX-1 were found in dHPC when compared to cHPC. After expansion procedure HPC progenitors expressed known oval-cells markers such as alpha-fetoprotein and cytokeratine-19, as well as beta cell differentiation transcripts in both cHPC and dHPC. Insulin presence was detected in cell extracts and culture medium after 2wks expansion. Interestingly, dHPC showed about 4-fold higher insulin-content and insulin secretion when compared to cHPC. Our preliminary results suggest that hepatic progenitor cells derived from diabetic animals have a potential to express beta-cell like phenotype.

1279 DIFFERENTIATION OF RAT MULTIPOTENT ADULT PROGENITOR CELLS TOWARDS THE HEPATIC LINEAGE BY RECAPITULATING LIVER EMBRYOLOGY

Karen Pauwelyn1,2, Pau Sancho-Brú1, Kartik Subramanian1, Vicky Raets1, April Breyer1, Molly Nelson-Holte2, Chris Verfey1, Johan Fever2, Frederik Nevens3, Catherine Verfaillie1

Background/Aims. Bone marrow derived Multipotent Adult Progenitor cells (MAPCs) might represent a unique in vitro system to explore early lineage commitment and mammalian development. The aim of this study was to check whether the current knowledge on liver development could be applied to optimize in vitro the differentiation of rat MAPCs towards hepatic-like cells. Methods. The differentiation protocol was divided into 4 consecutive steps. First, Wnt3a and ActivinA guide the cells towards a mesendodermal fate. Second, specification of the ventral foregut endoderm to hepatic endoderm was mimicked by adding bFGF and BMP4, which are known to be secreted by the cardiac mesoderm and septum transversum mesenchyme in vivo. Next, aFGF, FGF4 and FGF8b were used as they enrich embryonic liver cultures for bipotent and unipotent hepatocyte progenitors. Finally, further maturation was induced by culturing the cells in the presence of HGF and Follistatin, the latter to inhibit cholangiocyte differentiation. Aside from testing these cytokines, we varied basic media components, such as insulin, serum, glucose and dexamethasone. As a control, cells were cultured in the same medium and at the same cell density, but in the absence of cytokines. Results. Using this cytokine combination, a mixture of immature and mature hepatocyte-like cells was gradually obtained. Mesendodermal markers such as Goxosecoid, CXC4, 1m42f2 were transiently expressed, suggesting the formation of definitive endoderm. Low percentage of serum, high concentration of dexamethasone and glucose favoured expression of mature liver transcripts. Cells displayed hepatic morphology on electronic microscopy. Besides hepatic-like cells, the culture also contained mesodermal-derived cell types, which might exert a positive effect on the hepatic maturation. Albumin, CK18, HNF1 and alpha-fetoprotein were seen on the protein level by immunohistochemistry. Differentiated cells secreted albumin, conjugated bilirubin and stored glycogen. In the absence of cytokines, liver markers were also expressed, but at a lower level and at a later time point during differentiation as compared to the multipotent protocol. Conclusion. Liver development is a modular process, requiring multiple cytokines and cell interactions, each playing a significant role at distinct time points during embryogenesis. We found that differentiation of rat MAPCs towards the hepatocyte lineage mimics liver embryology, making them a useful tool to study mammalian development in vitro. In the future, this strategy will also be applied to generate hepatic-like cells from other types of pluripotent stem cells.

1280 DIFFERENTIAL ACETAMINOPHEN-INDUCED HEPATOXICITY BETWEEN TWO TYPES OF DIETARY STEATOSIS OF THE LIVER IN MICE

Yuqing Wang1, Makoto Oketani1, Masahisa Horiiuchi2, Yasushi Imamura2, Akihiro Moriuchi1, Susumu Hasegawa1, Hirofumi Uto1, Akio Ido1, Hirohito Tsoubochi1; 1Digestive and Life-style related Diseases, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, Japan; 2Environmental Medicine, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, Japan; 3Kagoshima Kouseiren Medical Health Care Center, Kagoshima, Japan

Background: Nonalcoholic fatty liver disease (NAFLD) is a common disease recognized as a major health problem. Acetaminophen (APAP) is an often used analgesic and antipyretic that can cause intoxication through overdosing. However, whether livers with steatosis are more susceptible to APAP-induced liver injury has not been clarified. Aim: To generate different fatty liver models by feeding a fat rich and fructose rich diets and then evaluate APAP-induced hepatotoxicity. Methods: Seven week old C3H/HetJc/Jc male mice were divided into 3 groups by different diets: low protein diet (LPD, protein: 52g/kg), low protein+high-fat diet (LP-HFD, soybean oil: 312g/kg), and low protein+high fructose diet (LP-HF5D, fructose: 682g/kg). After feeding for 3 weeks, the mice were
treated with APAP (120 mg/kg) by intraperitoneal injection to induce liver injury. After 6 hours mice were sacrificed and blood and liver specimens collected. The plasma levels of ALT, AST, triglyceride (TG), total cholesterol (TC), glucose, insulin, total protein, and albumin were determined. The hepatic contents of TG and TC in each group of pretreated mice were measured. Real time RT-PCR was carried out to evaluate the pretreated hepatic expression of fatty acid synthase (FAS), phosphoenolpyruvate carboxykinase (PEPCK), glucose 6-phosphatase (G6Pase), CYP1A1, and CYP2E1 in pretreated mice. Results: The liver tissue specimens of the LP-HFD and LP-HFrD-fed mice revealed significant fatty infiltration. The hepatic contents of TG and TC in both these mouse groups were significantly higher than those in LPD-fed mice. Real time RT-PCR analysis demonstrated a higher expression of FAS in mice fed LP-HFrD than those fed LPD and LP-HFD (1.8-fold and 2.0-fold, respectively). A higher expression of G6Pase in mice fed LP-HFD than in those fed LPD and LP-HFD (1.7-fold and 3.0-fold, respectively) was also revealed. There was no significant difference in basal levels of CYP2E1 in the livers among the three groups. By contrast, CYP1A1 expression in mice fed LP-HFD was higher than LPD and LP-HFrD (2.5-fold and 1.8-fold, respectively) fed mice. The levels of ALT 6 hours after APAP gavage in the LP-HFD group was significantly higher than in LPD (8093 ± 1862 IU/L, n=5) than those in LPD (12±2 IU/L, n=4) (p<0.0001) and LP-HFrD (40±25 IU/L, n=5) (p<0.0001) groups. Conclusions: We succeeded in generating two types of mouse fatty liver model with different glucose and fatty acid metabolisms. Our results showed that hepatic steatosis elicited by low protein and high fat diets significantly increased APAP-induced hepatotoxicity. This effect was independent of CYP2E1 expression, which stimulated APAP bioactivation.

REPEATED EXPOSURE TO ACETAMINOPHEN PROTECTS AGAINST A SUBSEQUENT LETHAL DOSE THROUGH SELECTIVE DEPLETION OF CYTOSOLIC GLUTATHIONE

Marjorie Bon Homme, Sreeleatha Channareddy, William W. Tucker, Roland Valdes, Mark W. Linder; Pathology and Laboratory Medicine, University of Louisville, Louisville, KY

Mechanisms to account for unintentional death and hepatotoxicity from acetaminophen (APAP) exposure are not understood. Our laboratory has established an animal model of adaptive tolerance to APAP exposure in order to identify protective mechanisms that when disabled through genetic variation or environmental conditions, subject the individual to increased risk of hepatotoxicity. In this model, male BALB/C mice are divided into four groups of 5 animals each: tolerated, tolerated-plus-lethal dose (tolerated LD), naive and naive-lethal dose (naïve LD). Both the tolerated and tolerated LD groups were treated with increasing doses of APAP intraperitoneally as follows: 50 mg/kg for two days, 100 mg/kg for two days, 250 mg/kg for two days. On the seventh day, the tolerated group received a saline injection while the tolerated LD group received a 350 mg/kg dose of APAP. The naive and naïve LD groups received saline for six days. On the seventh day, the naive LD group received a lethal dose of APAP while the naïve group received saline. Six hours following the lethal dose, two animals from the naïve LD group had died. No animals died from the naïve, tolerated and tolerated LD groups and their livers were lighter in color and weight. Biochemical analysis revealed selective cytoplasmic glutathione depletion. Naïve animals showed a decrease in mitochondrial (29.4 +/- 5.4 to 11.9 +/- 9.2 μmole/gram total protein) but no change in cytoplasmic (34.4 +/- 10.5 to 15.2 +/- 13.6 μmole/gram total protein) total glutathione pools when challenged with a lethal dose of APAP. In contrast, tolerated animals showed increased mitochondrial (48.9 +/- 4.1 μmole/gram total protein) and cytoplasmic (56.2 +/- 14.3 μmole/gram total protein glutathione. When challenged with a lethal dose, tolerated animals showed a decrease in cytoplasmic (38.5 +/- 6.4 μmole/gram total protein) and increase mitochondrial (82.1 +/- 8.8 μmole/gram total protein) glutathione. Thus acquired tolerance to APAP involves mitochondrial resistant to glutathione depletion. This finding is significant in light of prior work demonstrating that depletion of mitochondrial glutathione sensitizes the hepatocyte to TNF dependent killing. In these same animals, we have conducted microarray gene analysis and comparing naïve to tolerated-lethal dose animals. Interestingly, major changes in mRNA expression in the tolerated animals are linked to TNF signaling. We hypothesize that selective depletion of cytosolic glutathione while favorable to TNF-induced apoptosis plays a part in the protective mechanism of adaptive tolerance to APAP. Future studies will involve the measurement of caspase 3 to assess apoptosis.

1282
MALLORY BODY FORMATION IS AN EPIGENETIC PHENOMENON WHICH IS PREVENTED BY TREATMENT WITH SAME

Joan V. Oliva, Barbara A. French, Fataneh Amid, Fawzia Bardag-Gorce, Jun Li, Jennifer Dedes, Laron McPhaul, Samuel W. French; Pathology, Harbor-UCLA Medical Center, Torrance, CA

Background: Mice fed DDC (0.1%) for 10 weeks, and then withdrawn from the drug for 1 to 4 months, retain the ability to form Mallory Bodies (MBs) when the drug is refed for 7 days. The liver cells that form MBs increase and partially replace normal liver cells when the MBs form. Method: Microarray analysis was done with RNA from livers of mice treated with DDC and DDC+SAME. The hepatocytes forming MBs were identified immunohistochemically by over expressing ubiquitin in the cytoplasm. Results: Microarrays analysis of mice livers showed that MB formation was associated with changes in expression of a large number of genes. FAT10 was increased by 215 fold. FAT10, a new marker, identified these cells using an antibody to FAT10 (UbD or DiUbiquitin). FAT10 is over expressed in 90% of Human HCCs. This over expression was measured using Quantitative RT-PCR for the drug fed and drug primed mice which were refed the drug for 7 days. At this time MB formation was observed. When drug primed mice were refed DDC with S-adenosylmethionine (SAME) (7g/kg body weight), the over expression of FAT10 was prevented and MB formation was inhibited to the levels of the control mice. The inhibition of FAT10 over expression by SAME feeding was documented both by immunohistochemically (number of positive staining hepatocytes) and Quantitative RTPCR. Drug primed mice withdrawn from the drug for 8 to 9 months retained FAT10 positive hepatocytes. Hepatocellular tumors developed and stained positive for FAT10. A similar pattern of gene expression was found when KLF6, Alpha feto-protein and GSTmu2 were measured by Quantitative RTPCR. Conclusion: FAT10 is a marker for MB formation. FAT10 positive cells persist 9 months after drug withdrawal and form hepatocellular tumors. FAT10 over expression in drug primed livers is prevented by SAME, which induces hypermethylation of DNA and histones. This suggests that
1283
THE SPECTRUM OF LIVER DISEASE IN HIV-INFECTED INDIVIDUALS IN EAST AFRICA

Ponsiano Ocama, Jordan J. Feld, Michael Katwere, Theresa Piloya, Kenneth Opio, Andrew Kambugu, Elly Katabira, David L. Thomas, Robert Colebunders, Allan Ronald; Infectious Disease Institute, Mulago Hospital, Makerere University, Kampala, Uganda

Background: As patients are surviving longer, liver disease has emerged as an important cause of morbidity and mortality in patients with HIV infection. Despite the high burden of HIV in East Africa, little is known about the causes and consequences of liver disease in the HIV-infected population, partially because scarce resources often limit the extent of investigation and available treatment options. Aims: To define the spectrum of symptomatic liver disease in a large cohort of HIV-infected individuals in Kampala, Uganda. Methods: Patients presenting with jaundice, right upper quadrant (RUQ) pain, ascites and/or tender hepatomegaly were recruited for study participation. All study subjects underwent investigations to determine the cause of liver disease including HBV/HCV serology, liver enzyme evaluations, abdominal ultrasound and liver biopsy when indicated. Results: From May 2004 to March 2005, 8,715 HIV-positive patients (5,585 64% female) were seen at the Infectious Disease Clinic of Mulago hospital, 1,560 (18%) of whom were on antiretroviral therapy (ART). 77 (0.8%) patients met study inclusion criteria: 33 jaundice, 47 RUQ pain, 16 ascites and 5 tender hepatomegaly. The mean age was 37 years and 62 (81%) had a CD4 count below 200. Drug-induced liver injury (DILI) was the most common etiology (INH 10, nevirapine 7, both 5), presenting with jaundice in 14 and RUQ pain in the others and resolving in all patients with drug discontinuation. A cholestatic pattern predominated in patients taking INH (mean ALP 379 IU/L, ALT 92 IU/L) while a mixed pattern was seen in those taking nevirapine (mean ALP 733 IU/L, ALT 443 IU/L). 11 patients were HBsAg positive, 8 of whom had no other cause for liver disease identified. 7 patients presenting with RUQ pain, fever, hepatomegaly and high ALP (mean 2147 IU/L) (plus jaundice in 3), were treated for presumed tuberculous hepatitis and all responded well. Other diagnoses included: alcoholic liver disease (4), liver abscess (2), AIDS cholangiopathy (1), schistosomiasis (1), adenoma (1) and hemangiomia (1). Notably 12 (16%) patients died during follow-up, including 4 with hepato cellular carcinoma (HCC) and 3 with end-stage liver disease. Conclusions: Symptomatic liver disease is relatively common in HIV-infected individuals in Uganda and may portend a poor prognosis. Drug-induced liver injury is the most common cause and responds well to drug discontinuation. TB hepatitis should be considered in patients with a cholestatic presentation.

1284
QUANTITATIVE PROTEOMIC ANALYSIS OF THE ETHANOL RESPONSE IN HEPATOCYTES USING THE ISOTOPE CODED AFFINITY TAG METHOD AND A SYSTEMS BIOLOGY APPROACH

Wei Yan2, Paul Shannon2, Jose Moron3, Laura Conde de la Rosa1, Natalia Nieto1; 1Medicine/Liver Diseases, Mount Sinai School of Medicine, New York, NY; 2Institute for Systems Biology, Seattle, WA; 3Center for Addiction Research, The University of Texas Medical Branch, Galveston, TX

The mechanism of the ethanol–mediated liver injury involves many pathways not exclusive of one another that function in a coordinate manner. The aim of this work was to identify new proteins and pathways involved in the mechanism of ethanol toxicity in hepatocytes and examine the potential crosstalk between such pathways. We applied the isotope coded affinity tag (ICAT) proteomic method to compare protein abundance in hepatocytes from rats fed the Lieber-DeCarli diets. Hepatocytes were isolated and harvested immediately after perfusion. Proteins were labeled with the cleavable ICAT reagent followed by trypsin digestion. The ICAT labeled peptides which carry biotin tags were fractionated by cation exchange chromatography and purified by avidin affinity chromatography. Peptide mixtures were subjected to micro capillary HPLC and to mass spectrometry analysis using LTQ. Software tools available at the Seattle Proteome Center (Institute for Systems Biology) were used in the data analysis: 1) peptide tandem mass spectra matching to specific sequences in a database using SEQUEST, 2) assignment of a probability to the identified peptide sequence using PeptideProphet, 3) assignment of an overall probability to the protein identification using ProteinProphet, 4) calculation of ICAT ratio using the ASAP Ratio and EXPRESS programs, and 5) use of the ISB Experiment Analysis Management System. The ICAT method and the global proteomic analysis led to identification of more than 450 proteins from control and ethanol–treated hepatocytes with probability scores >0.5 (<5% error rate). Among the identified proteins were several well known alcohol regulated proteins such as those involved in fatty acid metabolism, oxidative phosphorylation, PPAR signaling pathway, and cytochrome P450 metabolism. Novel mitochondrial and ribosomal proteins were up- or down-regulated by alcohol treatment. Proteins identified by ICAT were explored for function, interactions, and pathway membership using a variety of annotation data sources integrated via the Gaggle http://gaggle.systemsbiology.org. Protein identifiers were mapped to Entrez GenIDs, which were then ‘broadcast’ to KEGG (for metabolic pathways), HPRD (for protein interactions), Bioconductor GOstats (for enriched molecular function and biological process) and EMBL STRING (for gene and protein associations). The resultant network of associations and interactions was broadcast back to cytoscape for further study, leading to the identification of putative novel and liver-specific regulatory components of the ethanol response. We are currently blocking critical pathways to assess the potential prevention of alcoholic liver injury.

B-LYMPHOCYTES AS AN IN-VITRO MODEL TO STUDY INTERINDIVIDUAL VARIATION IN SENSITIVITY TO ACETAMINOPHEN TOXICITY

Sara K. Peterson1, Ray L. Hawke2, Paul B. Watkins3; 1School of Medicine, Boston University, Boston, MA; 2School of Pharmacy, University of North Carolina, Chapel Hill, NC; 3School of Medicine, University of North Carolina, Chapel Hill, NC

Background: The dose of acetaminophen (APAP) required to cause liver injury varies among people. Indeed, some develop elevations in serum alanine aminotransferase with recurrent therapeutic dosing (JAMA 5:296(1):87-93, 2006). To define mechanisms underlying this variation in sensitivity, liver tissue is most relevant but is rarely available. Peripheral blood mononuclear cells (PBMCs) may represent a suitable alternate tissue for study because they express relevant metabolic pathways, including CYP enzymes and glutathione, plus they are easily accessible. Furthermore, loss of PBMCs accompanies APAP hepatotoxicity in mice. Goals: To determine if there exist interindividual differences in PBMC sensitivity to APAP toxicity and whether sensitivity varies by PBMC type. Methods: Human PBMCs were isolated by centrifugation on Ficoll-PaqueTM Plus and cultured for 48hrs with varying concentrations of APAP (1-10mM). The Cell Titer Blue® Assay and FACSScan analysis with propidium iodide were used to quantify cytotoxicity after APAP exposure. CD-specific antibodies were used to distinguish effects on subpopulations of PBMCs. Dynal Bead technology was used to isolate B lymphocytes from PBMCs. Statistical estimates of variance and confidence intervals were computed by fitting a single-group repeated-measures analysis of variance model in which "sensitivity" was the dependent variable. Results: Among 10 healthy adult volunteers, the APAP concentration required to kill 40% of the PBMCs at 48hrs ranged from 3.3mM to 16.6mM and the percent cell death resulting from 48hr exposure to 10mM ranged from 28% to 69%. Relative susceptibility "phenotype" was not changed with 3 repeat measurements separated by one week [n=5; intra-subject variance of 9.32% viability squared vs. inter-subject variance of 92.5% viability squared]. FACSScan analysis identified B lymphocytes as the subpopulation of PBMCs most susceptible to APAP toxicity. In contrast, T lymphocyte viability was relatively unchanged even at the maximal APAP concentration (10mM). Isolated B lymphocytes confirmed similar susceptibility to APAP toxicity as observed within PBMCs (>60% killed by 10mM APAP at 48hrs). Conclusion: There exists interindividual variation in the susceptibility of PBMCs to APAP-induced cytotoxicity and this phenotype appears to be reproducible within an individual. B lymphocytes are most sensitive to APAP toxicity, and may be the preferred cell population for mechanistic studies. These observations will have implications for the study of hepatotoxicity since B lymphocytes are being immortalized from all patients enrolled in the Drug Induced Liver Injury Network study.

ALCOHOL INDUCES GLOBAL HEPATIC PROTEIN HYPERACETYLYATION

Blythe D. Shepard1, Dean J. Tuma2, Pamela L. Tuma1; 1Biology, The Catholic University of America, Washington, DC; 2Internal Medicine, University of Nebraska Medical Center, Omaha, NE

Chronic alcohol consumption can lead to serious liver disease. Although the disease progression is clinically well-described, the molecular basis for alcohol-induced hepatotoxicity is not well understood. Previously, we determined that microtubules were more highly acetylated and more stable in ethanol-treated WIF-B cells, an emerging model system for studies on liver injury. We further determined that microtubules were hyperacetylated to the same extent in livers from ethanol-fed rats indicating this result has physiologic importance. Besides tubulin, there is a growing number of proteins known to be acetylated on lysine residues including histones, transcription factors, nuclear import factors and p53. Large families of acetyltransferases and deacetylases have also been identified whose substrate specificities are not yet well defined. With this growing number of acetylated proteins and large number of modifying enzymes, it is likely that many other hepatic proteins are hyperacetylated in ethanol-treated cells. In support of this conclusion, we found in this study that nuclear histone deacetylase activity was impaired 35% in ethanol-treated WIF-B cells. In order to identify other hyperacetylated proteins, we have been immunoblotting samples prepared from livers of control and ethanol-fed rats with antibodies specific for acetylated lysine residues. Our analysis started globally where liver whole homogenates were compared. In general, the same 10-16 proteins ranging in molecular weight from 12-175 kDa were more highly acetylated in ethanol-treated homogenates. For most proteins, acetylation was enhanced 2-3 fold, but in some cases, acetylation was increased >20-fold. Among all samples examined, a cluster of 5 bands ranging from 30-45 kDa and a protein of 25 kDa were consistently hyperacetylated 2-3 fold and proteins at 175 and 12 kDa were hyperacetylated 2-10 fold. To further characterize the hyperacetylated proteins, we prepared nuclear, cytosolic and total membrane fractions by differential centrifugation. The 12 kDa protein was exclusively localized to the nuclear fraction as well as an additional cluster of hyperacetylated proteins ranging from 15-22 kDa that may likely be histones. The 175 kDa protein was recovered mainly in the membrane fraction whereas the 30-45 kDa cluster and the 25 kDa protein were mainly cytosolic. These results confirm our hypothesis that ethanol induces hyperacylation of a range of hepatic proteins. Such changes in acetylation likely have profound effects on hepatocyte function. Studies are underway to identify these proteins and determine how hyperacetylation alters proper hepatic function.

USEFULNESS OF FIBROSCAN FOR THE FOLLOW UP OF PATIENTS TREATED WITH METHOTREXATE

David Laharie1, Edouard Chabrun1, Thierry Schaeverbeke2, Thomas Hubiche2, Marie-Sylvie Douret3, Maïté Longy2, Jean-Luc Pellegrin1, Julietteoucher1, Laurent Castera1, Florence Saluam1, Sandrine Villars1, Frank Zerbitz1, Victor de Ledingen1,2; 1Hepato-Gastroenterology, Hospital Haut Leveque, Pessac, France; 2Rhumathology, Hospital Pellegrin, Bordeaux, France; 3Dermatology, Hospital Saint Andre, Bordeaux, France; 4Dermatology, Hospital Haut Leveque, Pessac, France; 5Hepato-Gastroenterology, Hospital Saint Andre, Bordeaux, France; 6INSERM U889, Universite Victor Segalen, Bordeaux, France

Introduction: Liver stiffness measurement using FibroScan allows evaluating liver fibrosis. Recently, its has been shown that FibroScan could be useful for the follow-up of patients with Crohn’s disease treated with Methotrexate (MTX) and that significant fibrosis was rare in these patients (Laharie et al, 2006).
The aim of this prospective study was to evaluate significant fibrosis using FibroScan in a large cohort of patients with various diseases treated with MTX compared to patients without MTX. Methods: From January 2005 to April 2007, all consecutive patients treated with more than 1500 mg of MTX (group I, n=108) were compared to controls who never received MTX or received MTX ≤ 1500 mg (group II, n=199). In all patients, liver fibrosis was evaluated using FibroScan. For the diagnosis of significant fibrosis, published cut-off (> 8.7 kPa) was used (Ziol et al. Hepatology 2005). Results: A total of 307 patients (117 males, mean age 50.4 years, mean BMI 24.6 kg/m2, Crohn’s disease (n=85), psoriasis (n=73), rheumatoid arthritis (n=69), spondylarthritides (n=19), other inflammatory diseases (n=61), mean total dose of MTX in group I 3683 mg for 275 weeks) were included. Liver stiffness values ranged from 1.8 to 25.7 kPa (median: 4.4 kPa). For all patients, no correlation was observed between the total dose of MTX and FibroScan (Kendall Tau-b=0.034). Between group I and II, no difference was observed for liver fibrosis assessment. In group I, patients (n=6) with liver stiffness measurement > 8.7 kPa had a total dose of MTX between 2220 and 3240 mg. One patient had cirrhosis on liver biopsy. For others, 4/5 had BMI > 25 kg/m2 and 4/5 had no or mild fibrosis using Fibrotest. In group II, 4/10 patients with liver stiffness measurement > 8.7 kPa had never received MTX. For others (mean dose: 648 mg), one had cirrhosis on liver biopsy. For others, 4/5 had BMI > 25 kg/m2 and 5/5 had no or mild fibrosis using Fibrotest. Conclusion: In patients treated with MTX, whatever the indication of MTX treatment, there is no increased risk of significant fibrosis. According to these results, liver biopsy could be avoided during the follow-up of patients treated with MTX. A liver biopsy should be performed only in patients with persistent liver enzyme abnormalities or elevated liver stiffness measurement.

1288 RELATIONSHIP BETWEEN MEDICATION DOSE AND IDIOSYNCRATIC DRUG INDUCED LIVER INJURY (DILI)
Craig Lammert1, Einar Bjornsson2, Chandan Saha3, Naga P. Chalasani1; 1Indiana University School of Medicine, Indianapolis, IN; 2Sahlgrenska University Hospital, Gothenburg, Sweden

Introduction: Idiosyncratic DILI by definition is not dose-related but there are anecdotes suggesting that daily medication dosage may play a role in the pathogenesis of idiosyncratic DILI. Aim: To examine the relationship between the daily dose of oral prescription medications and the reports of hepatic adverse events. Methods: From a well known public database, we extracted the names of top 200 brand name and 200 generic drugs by prescription volume in the United States. After excluding the duplicate entries and non-oral medications, 234 medications were available for further consideration. These medications were categorized into <10 mg, 10-50 mg, >50mg according to recommended daily dosage. We subsequently reviewed the “DRUGDEX” to extract the details of reported hepatic adverse events for each medication belonging to these 3 groups. DRUGDEX, a comprehensive pharmaceutical database, consists of package insert data and published medical literature. Cochran-Armitage trend test and logistic regression analyses were done to test the association between outcome events and dosage groups. Results: Among 3 groups, there was no difference in the number of prescriptions filled in 2005 (p=0.35). The relationship between 3 dosage groups and reports of hepatic adverse events are shown in the table below. Logistic regression analyses showed that, compared to < 10 mg/daily group, more medications in the > 50 mg/day group had reports of increased ALT (OR: 3.28, 95% CI 1.62-6.63, p=0.001), liver failure (OR: 2.35, 95% CI 1.02-5.40, P=0.045), death” (OR: 3.09, 95% CI 1.18-8.04), and liver transplant (OR: 10.45, 2.3-47.44, P=0.002. There was no statistically significant difference between < 10 mg/d and 10-50 mg/d groups. Summary: (1) Significantly more number of medications given at daily doses > 50 mg have been associated with drug-induced liver failure, necessity for liver transplantation, and liver-related deaths, (2) daily dose had inconsistent relationship with elevated ALT, and (3) daily dose was not associated with cholestatic jaundice. Conclusion: We found a significant relationship between daily dose of oral medications and reports of hepatic adverse events. More studies are needed to validate and explore the significance of our observations.

1289 THE CHOICE OF CLINICAL LABORATORY MAY CHANGE STUDY OUTCOME: AN INTER-LABORATORY EVALUATION OF AMINOTRANSFERASE MEASURES
Jody L. Green, Elizabeth Campagna, Gregory M. Bogdan, Kennon Heard, Richard C. Dart; Denver Health Rocky Mountain Poison and Drug Center, Denver, CO

Throughout the United States, clinical laboratories establish reference ranges, commonly referred to as the “normal” range for aminotransferase assays. Guidelines for determining reference ranges have been published but it is unknown how many or which laboratories follow the guidelines. Aminotransferase reference ranges vary between laboratories and may lead to difficulties in the interpretation of patient data in both clinical management and research. Drug-induced hepatotoxicity, as judged by alanine aminotransferase (ALT) serum activity in comparison to the reference range, is the single most common adverse effect leading to withdrawal of FDA-approved drugs. The purpose of this study was to determine if the classification of samples as “abnormal” would differ between two laboratories. We used 65 serum samples collected in a randomized clinical trial. Split samples were sent to two clinical laboratories for ALT testing, each used different instruments and reagents and
had different reference ranges. One laboratory had a higher ALT upper limit of reference range (ULRR) and the other a lower ULRR. The samples were stratified into three groups by the original ALT value: 1) ALT ≤ lowest ULRR (n=15), 2) ALT > lowest ULRR and ≤ highest ULRR (n=34) and 3) ALT > highest ULRR (n=16). Fifty-five of the specimens were from male subjects. Subject age ranged from 23 to 61 years (median 42 years). The overall ALT mean between laboratories was significantly different (p<0.001). The proportion of specimens judged abnormal (ALT greater than the ULRR) was 9% and 71% for Laboratory A and B, respectively (p<0.001). The proportion of samples with an ALT greater than three times the ULRR was zero at Laboratory A and 9% at Laboratory B (p=0.026).

Results for serum aspartate aminotransferase activity were similar. Our results indicate the classification of a sample as normal or abnormal differs between laboratories and that a patient’s serum ALT may be misclassified as normal or abnormal depending on the specific laboratory performing the assay. Interpretation would particularly be uncertain in large databases of spontaneous reports such as the FDA Adverse Event Reporting System (AERS). Adoption of standardized reference ranges and methodology are needed to allow consistent interpretation of results for patients or studies that are performed by different laboratories.

**1290 INHIBITION OF ATM ACTIVITY AMELIORATES THE ETHANOL METABOLISM-MEDIATED CELL CYCLE ARREST**

Dahn L. Clemens1,2, Katrina J. Mahan1,2, Robert F. Nuss1, Michael F. Sorrell1, Dean J. Tuma1,2; 1Internal Medicine, University of Nebraska Medical Center, Omaha, NE; 2Research, Veterans Affairs Medical Center, Omaha, NE

Background: Chronic ethanol abuse results in hepatocyte injury and impairs hepatocyte replication. Impaired hepatocyte replication inhibits the replacement of cells lost to the toxic effects of ethanol. It has been shown that ethanol metabolism is responsible for the impairment of hepatocyte replication. We have shown that ethanol metabolism results in cell cycle arrest at the G2/M transition of the cell cycle and that this arrest is, in part, mediated by inhibitory phosphorylation of the mitotic cyclin-dependent kinase Cdc2 and its regulatory phosphatase Cdc25C. The checkpoint kinases, Chk1 and Chk2, phosphorylate Cdc25C, effectively rendering it inactive. Chk1 and Chk2 are in turn regulated by ataxia telangiectasia mutated (ATM) and ATM and Rad3-related (ATR) kinases. The purpose of these studies was to investigate the role of ATM in the ethanol-metabolism-mediated G2/M cell cycle arrest. Methods: Hep G2 cells that express either alcohol dehydrogenase (ADH) or both ADH and cytochrome P450 2E1, VA-13 and VL-17A cells respectively, were cultured for 4 days in the presence of 25 mM ethanol and/or 1 mM caffeine, an inhibitor of ATM. Immunoblots were performed to determine the effects of ethanol metabolism and inhibition of ATM. The effects of inhibition of ATM on the cell cycle and on Cdc2 was determined by monitoring the cell cycle progression of cultures and the phosphorylation state of Cdc2. Results: Culturing VA-13 and VL-17A cells in the presence of ethanol resulted in a 50-65% increase in the activity of ATM, and a corresponding increase in both Chk1 and Chk2. Additionally, ethanol metabolism resulted in a 3 to 4-fold increase in the inhibitory phosphorylation of Cdc2, and approximately 25-35% of the cells being arrested at the G2/M transition of the cell cycle. Inhibition of ATM resulted in approximately 50% of the cells being rescued from the G2/M cell cycle arrest, and almost completely ameliorated the inhibitory phosphorylation of Cdc2. Conclusions: Ethanol metabolism results in the activation of ATM. ATM can phosphorylate and activate the checkpoint kinases Chk1 and Chk2, ultimately resulting in the accumulation of the mitotic cyclin-dependent kinase, Cdc2, in the inactive phosphorylated form. This may, in part, explain the ethanol metabolism-mediated impairment in replication. The inhibition of hepatocyte replication may be important in the initiation and progression of alcoholic liver injury. Additionally, because ATM is activated in both VA-13 and VL-17A cells these data indicate that acetaldehyde has a significant role in this mechanism of ethanol metabolism-mediated cellular replication impairment.

**1291 GENETIC POLYMORPHISMS OF IL-10, IL-4 AND TNF-α AND SUSCEPTIBILITY TO DEVELOP DRUG-INDUCED IDIOSYNCRATIC LIVER INJURY (DILI)**

Ketevan Pachkoria1, Esperanza Crespo5,6, Francisco Ruiz-Cabello5,6, Yolanda Borrajo2, Alfonso Serrano4, Gloria Palas4, M.C. Fernández2, Manuel Romero-Gomez7, Ana Madrazo7, Jose Maria Navarro5, Joan Costa10, Nuria Lopez10, Maribel Lucena2, Raül J. Andrade2, Digestive Service, Hospital Universitario Virgen de la Victoria, Malaga, Spain; 2Clinic Pharmacology, University of Malaga, Malaga, Spain; 3Clinic Pharmacology, University of Almeria, Almeria, Spain; 4Inmunology, Hospital Virgen de la Victoria, Malaga, Spain; 5Clinic Pharmacology, University of Almeria, Malaga, Spain; 6Clinic Pharmacology, Hospital Virgen de las Nieves, Granada, Spain; 7Clinic Pharmacology, Hospital Virgen de las Nieves, Granada, Spain; 8Digestive Service, Hospital Valme, Sevilla, Spain; 9Clinic Pharmacology, University of Granada, Granada, Spain; 10Digestive Service, Hospital Costa del Sol, Malaga, Spain; 11Clinic Pharmacology, Hospital German i Tries, Badalona, Spain; 12Digestive Service, Hospital Torrecárdenas, Almeria, Spain

The aetiology of DILI is suggested to be multifactorial, determined by a combination of genetic, environmental and immunological factors. Emerging data indicate that immunoregulatory cytokines such as interleukin (IL) 10, IL-4 and tumour necrosis factor (TNF)α may be important candidates in determining susceptibility to develop DILI. Interleukin 10 (IL-10) is a potent anti-inflammatory Th2 cytokine that down-regulates the expression of major histocompatibility complex class I and class II molecules as well as the production of Th1 cytokines. Polymorphism of IL-10, IL-4 and TNFα is known to affect cytokine production. However, limited data exist on their effects in DILI appearance Aims: The aim of this study was to assess the relationship between polymorphisms involving three cytokine genes IL-10 (-1082 G/A), -819 C/T, and -592 C/A), IL-4 (-308 G/A) and TNFα (-308 G/A) and DILI susceptibility. Methods: Cytokine genotyping was analysed in genomic DNA by means of PCR-FRET in a total of 140 DILI patients and 175 healthy controls. An analysis in a subset of 29 patients with amoxicillin-clavulanate hepatotoxicity was also performed. Results: No
differences between allele frequencies, genotypes and haplotypes were found between DILI and healthy controls. Patients with cytokine gene polymorphisms did not differ in regard to clinical presentation of DILI, type of injury and outcome. When analysed by IL-10 haplotype carrier state, we identified the possible association between the low IL-10 producing haplotype (ACC, ATA) and absence of eosinophilia (p= 0.0004; OR 5.3, 95% CI 2.05-13.67). This association remained significant for cases of amoxicillin-clavulanate hepatotoxicity. Comparison of low IL-10 producing haplotype carriers and absence of eosinophils with high IL-10 producing haplotypes showed no difference in age, gender and duration of treatment between groups. Interestingly, cases of fulminant liver failure and transplant cases (n=3) as well as severe DILI cases (high bilirubin, altered prothrombin time) (n=5) were classified as low IL-10 producing haplotype. Searching in the general Registry database of Hepatotoxicity, out of 591 DILI patients 36 (6%) had a fatal outcome (death, transplant or fulminant liver failure) and none of them presented eosinophilia. While 113 patients out of the rest 555 (20%) had eosinophilia and a more favourable outcome. Conclusions: Our results show that IL-10, IL-4 and TNFα polymorphisms might not be predictable potential risk factors for DILI. Absence of eosinophilia in low IL-10 producing haplotype, which is compatible with an accelerated Th1-type response, might favour a worst DILI outcome. FIS 04/1759

1292 GILBERT’S SYNDROME ASSOCIATED VARIABILITY: COMBINATION OF UDP GLUCURONOSYLTRANSFERASE (UGT) 1A1 AND UGT1A7 GENE POLYMORPHISMS INCREASE THE RISK OF IRINOTECAN TOXICITY

Tim O. Lankisch, Christoph Schulz, Thomas Zwinger, Thomas J. Erichsen, Michael P. Manns, Volker Heinemann, Christian P. Strassburg

Background: Gilbert’s syndrome is characterized by the absence of severe liver disease and is associated with a functional promoter polymorphism (SNP) of the UDP glucuronosyltransferase (UGT) 1A1 gene leading to a reduced glucuronidation which potentially impact a broad array of therapeutic range. This is potentially relevant for hepatological therapeutic range. Instead, enhanced glucuronidation and physiologically plausible risk factor for irinotecan toxicity. Based on the role of UGT1A7 the UGT1A1/UGT1A7 SNP combination haplotype is demonstrated to be a superior risk predictor than UGT1A1*28 alone, which contributes to the therapeutic individualization of this drug with a narrow therapeutic range. This is potentially relevant for hepatological patients undergoing chemotherapy.

1293 ACETAMINOPHEN BIOTRANSFORMATION AT SINGLE AND REPEAT MAXIMUM DOSES IS SIMILAR BETWEEN ADULTS WITH AND WITHOUT CHRONIC LIVER DISEASE

Cathy K. Gelotte, Anthony R. Temple, Brenda A. Zimmerman, John T. Slattery; McNeil Consumer Healthcare, Fort Washington, PA; Departments of Pharmacology & Medicine, School of Medicine, University of Washington, Seattle, WA

Background & Aim: Acetaminophen toxicity is understood to be dose dependent. Hepatotoxicity is not imparted directly by acetaminophen concentrations, but rather by the activated metabolite, NAPQI, if not adequately detoxified by glutathione after excessive overdoses. The question of whether the diseased liver can adequately detoxify therapeutic doses of acetaminophen was addressed in this study by measuring the amounts, fractions of dose, and formation clearances of metabolites produced after single and repeat dosing of acetaminophen at the maximum-labeled daily dose (4 g/d) for four days. Methods: Data for 12 subjects diagnosed with hepatocellular cirrhosis secondary to hepatitis C and/or alcohol abuse, and a Child-Pugh score of 7 to 9, indicating moderate hepatic impairment, were compared with 13 healthy matched-control subjects. After the single and final repeat 1 g doses, serial blood and pooled urine samples were collected for 36- and 24-h, respectively. They were assayed for acetaminophen and metabolites. Amino- transferases and clinical adverse events were monitored during the study. Results: Analysis of variance detected no differences in mean fractions of metabolites excreted, including thiols, between groups after single or repeat doses. Only the amount of unchanged acetaminophen excreted was statistically higher (p=0.0035) in carriers of the UGT1A risk alleles, who also had significantly higher rate of dose reductions. Conclusion: The association of irinotecan toxicity with a combination of reduced function UGT1A1 and UGT1A7 SNPs represents a physiologically plausible risk factor for irinotecan toxicity. Based on the role of UGT1A7 the UGT1A1/UGT1A7 SNP combination haplotype is demonstrated to be a superior risk predictor than UGT1A1*28 alone, which contributes to the therapeutic individualization of this drug with a narrow therapeutic range. This is potentially relevant for hepatological patients undergoing chemotherapy.

1294
METABOLOMIC ANALYSIS OF URINE AND LIVER AFTER CHRONIC ALCOHOL TREATMENT IN C57BL/6J MICE
Blair U. Bradford, Jun Han, Oksana Kosyk, Svitlana Shymonyak, Jason Winnike, Hiroshi Kono, Thomas M. O’Connell, Ivan Rusyn; 1Environmental Sciences and Engineering, Univ. N. Carolina, Chapel Hill, NC; 2Metabolomics Facility, Univ. N. Carolina, Chapel Hill, NC; 3First Dept of Surgery, University of Yamanashi, Yamanashi, Japan

Rodent models of alcohol-induced liver injury have been invaluable for understanding the mechanisms of this disease in humans. While the intragastric enteral alcohol feeding model (Tsukamoto-French) mimics liver injury in alcoholics, one criticism of this approach has been that it is not a normal feeding pattern for rodents. In this experiment we aimed to determine (i) whether a modified Lieber-DeCarli liquid alcohol-containing diet regimen results in a comparable degree of chronic liver injury; and (ii) what are the biochemical events evoked by this treatment. Male, C57BL/6J mice were fed an isocaloric control or alcohol-containing liquid diet with 35% of calories from corn oil, 18% protein and 47% carbohydrate/alcohol for up to 36 days ad libitum. Alcohol treatment was initiated at 7 g/kg/day and gradually reached a final dose of 21 g/kg/day. Urine samples were collected at 22, 30 and 36 days and in additional treatment groups, liver and serum samples were harvested at 28 days. In the alcohol group, a 5-fold increase in ALT and a 6-fold increase in liver injury score (necrosis, inflammation and steatosis) were observed. Metabolomic profiling was performed on liver and urine using Nuclear Magnetic Resonance (NMR) Spectroscopy and Electrospray infusion/ Fourier transform ion cyclotron resonance-mass spectrometry (ESI/FTICR-MS). In liver, alcohol had profound effects on metabolites. Glycogen levels were decreased which is consistent with stimulated glycolysis, a decrease in glucose and elevated lactate levels. Stimulated glycolysis can also account for an increase in amino acid metabolism giving rise to elevations in alanine, glutamate and glutathione. A secondary effect of stimulated glycolysis likely caused increases in valine, leucine and alanine. Taurine, which is a metabolite of glutathione, was also increased likely due to high levels of choline detected. The effect of increased glutamate could explain the increases in mitochondrial acetone production from ketogenesis. Alternatively, alcohol dehydrogenase-dependent alcohol metabolism could explain high levels of acetone due to elevated rates of ketogenesis. In urine, tyrosine, a marker of oxidative stress, was elevated and is a precursor for DOPA, epinephrine and thyroid hormones, all known to be altered by alcohol. Ethyl glucuronide was also markedly increased and is a known biomarker of alcohol exposure in urine. In summary, assessment of the biochemical networks affected by alcohol will enable interindividual comparisons of the metabolic differences and may provide insight into factors influencing susceptibility to alcohol-induced liver injury. (AA016258 and ES10126)

Davern; 1Duke Clinical Research Institute, Durham, NC; 2University of Connecticut, Farmington, CT; 3University of North Carolina, Chapel Hill, NC; 4University of Michigan, Ann Arbor, MI; 5UCSF, San Francisco, CA; 6Indiana University, Indianapolis, IN; 7NIDDK, Bethesda, MD

PURPOSE: We describe an empirical study to evaluate the reliability of the Roussel Uclaf Causality Assessment Method (RUCAM) in pedigree cases of drug-induced liver injury (DILI).

METHODS: The DILIN Retrospective study is enrolling cases of hepatotoxicity caused by isoniazid, phenytoin, clavulanate / amoxicillin and valproate occurring since 1994. These drugs are known to cause DILI, and have an identifiable clinical pattern of injury. Using the RUCAM, each case was adjudicated by three independent reviewers; after an interval of at least 4 months, they were re-adjudicated by the same reviewers. Simple descriptive statistics were used to summarize RUCAM differences between the two occasions and across the 3 reviewers. A random-effects regression model was applied for a formal reliability analysis; the upper 95% confidence limit (U95CL) was derived using bootstrapping methods.

RESULTS: Forty DILI cases were included (isoniazid=9, phenytoin=5, clavulanate / amoxicillin=15 and valproate=11). Mean age at onset was 44.8 [range=3.5 to 78.5] years; 68% female; 78% Caucasian and 15% African-American. mean BMI at onset was 28.5 [range=16.0 to 51.1] kg/m²; 28% had a prior history of a liver condition. All patients had at least one symptom including jaundice (73%), nausea (55%), and fever (18%); 18% had extrahepatic manifestations. Mean (s.d.) peak serum tests during the injury were: AST=1026 (1257), ALT=821 (799), AP=424 (456) /U/L and total bilirubin=14.2 (13.6) mg/dL. Cases were classified as cholestatic (28%), mixed (28%) or hepatocellular (44%). Using expert opinion achieved by consensus among DILIN hepatologists, causality was judged as: definite (26%), very likely (49%), probable (21%) and possible (5%). Mean (s.e.) RUCAM on the first review was 6.2 (0.2), and 6.4 (0.2) on the second review (p=0.99). On re-review by the same reviewer, however, there was complete agreement on only 26% of cases; changes greater than 2 points occurred in 19% of cases. On average, the maximum absolute value of the pairwise differences among the three reviewers was 3.1 on the first review and 2.7 on the second review. There was significant variation among the reviewers (p=0.03). The test-retest reliability was 0.52 (U95CL=0.69); the inter-rater reliability was 0.50 (U95CL=0.67).

CONCLUSIONS: A research instrument should achieve a test-retest reliability of at least 0.8 and an inter-rater reliability of 0.6. In well-recognized hepatotoxic drugs, however, the RUCAM met only the latter criterion. This raises questions about its suitability for assessing causality, and suggests that additional approaches should be considered. Supported by cooperative agreement, 5U01DK065176-04.

DETECTION OF ACETAMINOPHEN PROTEIN ADDUCTS IN SERUM DURING THERAPEUTIC DOSING OF ACETAMINOPHEN IN HEALTHY VOLUNTEERS

Laura James1,2, Pippa Simpson1,5, Susan Rahman2, Mark Russo4, Paul B. Watkins3, 1University of Arkansas for Medical Sciences, Little Rock, AR; 2Children’s Mercy Hospital, Kansas City, MO; 3University of North Carolina, Chapel Hill, NC; 4University of North Carolina, Greensboro, NC; 5Arkansas Children’s Hospital Research Institute, Little Rock, AR

Background: Acetaminophen (APAP) protein adducts in serum have been proposed to be pathognomonic for APAP liver injury. The goal of this study was to determine whether adducts could be detected in healthy volunteers treated with the maximum recommended daily dose of APAP. Methods: 52 healthy men and women were housed as inpatients for 14 days and received APAP 4 grams daily for 7 days (days 4 - 11). Blood was drawn for adduct and ALT measurements each morning. Patients were stratified by ALT responder status: responder (change in ALT > 2 fold baseline; n=14); non-responder (change in ALT within 1.5 fold baseline; n=15); intermediate (> 1.5 and < 2 fold baseline; n=13). 10 subjects received placebo. A pharmacokinetic analysis was performed, presented as mean (+/- SD). Results: For all subjects receiving APAP, adducts were elevated compared to placebo (p<0.05) by 18 hours of dosing (day 5) and remained elevated until discontinuation of APAP (range: 0.067 nmol/mL serum). The elimination half-life (t1/2) was 2.9 (+/- 2.1) days; the maximum adduct concentration (Cmax) was 0.29 (+/- 0.11 nmol/mL); the change in adduct between days 4 and 5 (delta 4-5) was 0.14 (+/- 0.07 nmol/mL adducts). The t1/2, Cmax, and delta day 4-5 were higher in responders, but this was not statistically significant. The area under the curve for adducts was higher for responders/intermediate-responders combined (p<0.05), compared to non-responders. Adducts were lower than values in adults with APAP related acute liver failure (1.0-40 nmol/mL), adduct elevation preceded ALT elevation (Figure). Conclusions: Adducts are a sensitive marker of APAP exposure in healthy adult volunteers that receive therapeutic doses of APAP. The pharmacokinetics of adducts suggest that factors other than the extent of adduct formation underlie ALT response. Further studies in “at risk” populations are warranted to determine the biological significance of adducts and increases in ALT subsequent to therapeutic exposure to APAP. Supported by DK067999.

ACETAMINOPHEN-PROTEIN ADDUCTS IN ALCOHOLIC PATIENTS RECEIVING ACETAMINOPHEN 4 G/DAY FOR 5 DAYS

Sean H. Rhyee1, Jody L. Green1, Laura James2, Kennon Heard1, Richard C. Dart1, 1Denver Health Rocky Mountain Poison and Drug Center, Denver, CO; 2Arkansas Children’s Hospital Research Institute, Little Rock, AR

Background: Acetaminophen-protein adducts (APAP-ADD) are formed when the toxic metabolite of acetaminophen (APAP) binds to intracellular proteins. APAP-ADD are detectable in the serum of patients with acetaminophen poisoning. Objective: To determine whether APAP-ADD are detectable in alcoholic patients taking therapeutic doses of APAP. Methods: This was a sub study in a randomized, placebo controlled trial where 47 adult patients admitted to a controlled access facility received 1 gram APAP (40 patients) or placebo (7 patients) 4 times per day for 5 days. All patients were considered alcoholics (defined by CAGE questionnaire or Brief Michigan Alcoholism Screening Test), and were dosed at an alcohol detoxification center within 12 hours of their estimated sober time. Medications were dispensed by the nursing staff. Serum samples were collected at baseline and at days 2, 4, 6 and 7 and analyzed for APAP-ADD and ALT. APAP-ADD were quantified using a HPLC-EC assay. Each subject was monitored for clinical signs of hepatic injury as well as a standardized laboratory evaluation. Results: All five serial samples were available for all subjects. At day 0, APAP-ADD were detected in four (10%) APAP and one (14%) placebo subjects. Three of these subjects (2 APAP, 1 placebo) had a detectable serum APAP level at baseline and another reported ingestion of an APAP product prior to study enrollment. By day 6 APAP-ADD were detected in all (100%) APAP subjects and 2 (28%) placebo subjects. Mean APAP-ADD levels in APAP subjects increased during APAP dosing, reaching a peak of 0.310 ± 0.118 nmol/mL serum at day 6. Mean APAP-ADD level in APAP subjects decreased to 0.242 ± 0.100 nmol/mL serum on day 7. APAP subjects had a slight increase in mean ALT values during the study, from 42.55 ± 37.74 IU/L at day 0 to 57.30 ± 53.80 IU/L at day 7. No consistent trend was seen in ALT values in placebo subjects. Discussion: Alcoholic subjects taking the maximal therapeutic dose of APAP for 5 days had increasingly detectable APAP-ADD. The adducts detected in the placebo subjects likely represent unreported acetaminophen consumption. Our findings suggest that APAP-ADD occur during metabolism of therapeutic amounts of acetaminophen and that a low level of adducts characteristic of repeat therapeutic exposure to APAP can be detected in the absence of clinically relevant changes in ALT. As overdose patients have serum adducts 3- to 20-fold higher than the levels reported here, future studies will be needed to differentiate adduct levels consistent with therapeutic exposure and adduct levels indicative of acetaminophen toxicity.

A HIGH BARRIER TO RESISTANCE MAY CONTRIBUTE TO THE ROBUST ANTIVIRAL EFFECT DEMONSTRATED BY R1626 IN HCV GENOTYPE 1-INFECTED TREATMENT-NAIVE PATIENTS

Sophie Le Pogam, Amritha Seshaadri, Alan Kosaka, Steven Hu, Hyunsoo Kang, Julian Symons, Klaus Klumpp, Nick Cammack, Isabel Najera; Roche Palo Alto LLC, Palo Alto, CA

R1626, a prodrug of R1479, is a potent inhibitor of HCV replication that has shown maximum mean (median) HCV RNA reductions of up to 3.7 (4.1) log10 following 2 weeks of monotherapy study, and 5.2 log10 following 4 weeks in combination with peginterferon alfa-2a (PEG-IFNα-2a) ± ribavirin (RBV) (phase 2A) in patients infected with HCV genotype 1. In vitro studies have identified NS5B polymerase amino acid substitutions, S96T or S96T/N142T, that result in 4-5-fold reduced sensitivity to R1479 as determined in the replicase assay. These mutations also resulted in a ~95% reduction in replication capacity compared to the wild type replicon. To study resistance development in vivo, phenotypic and genotypic analyses were performed on multiple serum samples from a total of 11 HCV patients treated with R1626 (3 from the monotherapy study and 8 from the combination study), who showed viral rebound before the end of treatment (defined as a sustained ≥ 0.5 log10 increase of viral load above nadir [lowest point], where nadir is a ≥ 0.5 log10 decrease from baseline). All samples tested in the HCV NS5B phenotypic assay were sensitive to inhibition by R1479 to a similar extent as the baseline samples and the 2 reference strains, Con1 and H77. Sequence analysis of the entire NS5B coding region revealed no known R1479 resistance mutations (S96T or S96T/N142T) or any other common amino acid substitutions. Three patients who failed to respond to R1626 (defined as <0.5 log10 decrease of viral load from baseline) had all received 500 mg of monotherapy. NS5B population sequence analysis and clonal sequence analysis of between 40–106 NS5B polymerase molecular clones for baseline samples of these 3 patients did not reveal pre-existing amino acid substitutions among the quasispecies of these patients that could be responsible for resistance to R1479. These findings are consistent with the sensitivity of these samples to inhibition by R1479 as observed in the phenotypic assay. In addition, sequence analysis demonstrated the absence of known R1479-resistance mutations in baseline samples of all patients who participated in both studies. In conclusion, there was no evidence for resistance selection to R1626 after 2 weeks of monotherapy or after 4 weeks in combination with PEG-IFNα-2a ± RBV. These findings suggest that there is a high barrier to the development of resistance to R1626 in vivo, that may contribute to the robust antiviral effect of this drug that has been observed in randomized clinical trials.

WHAT IS THE IMPACT OF HIGHER SENSITIVITY ASSAY ON RESPONSE-GUIDED THERAPY IN HEPATITIS C VIRUS (HCV)? COMPARATIVE ANALYSIS BETWEEN TAQMAN™ AND AMPLICOR™ TESTS FROM TWO LARGE RANDOMIZED INTERNATIONAL TRIALS OF PEGASYS® PLUS COPEGUS®

Christoph Sarrazin1, Mitchell L. Shiffman2, Stephanos J. Hadziyannis3, Amy Lin4, Giuseppe Colucci5, Hiroshi Ishida6, Stefan Zeuzem1; 1Department of Internal Medicine, J. W. Goethe-University Hospital, Frankfurt, Germany; 2Hepatology Section, Virginia Commonwealth University Medical Center, Richmond, VA; 3Henry Dunant Hospital, Athens, Greece; 4Roche, Nutley, NJ; 5Roche Molecular Systems-RIC, Rotkreuz, Switzerland; 6Roche, Basel, Switzerland

Background: HCV treatment is rapidly evolving from a fixed duration of peginterferon alfa-2a (40KD) plus ribavirin (RBV) (48wks for genotype [G] 1; 24wks for G2/3) to response-guided therapy (RGT), adjusting duration according to on-treatment virologic response at wk4 and wk12; rapid virologic response (RVR) and complete early virologic response (cEVR), respectively. RGT originally used sensitive PCR assays (e.g. COBAS Amplicor HCV, v2.0; detection limit 50 IU/mL). It is unclear how the more sensitive TaqMan assay (COBAS AmpliPrep/COBAS TaqMan HCV Test: detection limit 15 IU/mL) will influence RGT. We therefore reanalysed serum samples stored at −70°C from two large international studies, ACCELERATE (G2/3) and NV15942 (G1,2&3), and compared clinical outcomes when using Amplicor or TaqMan.

Methods: In ACCELERATE, TaqMan data were available from patients who had sufficient sample volume at baseline (BL; n=122) and wk4 (n=663). In NV15942, TaqMan data were available from patients who had BL, wk4, wk12, end of treatment (EOT) and end of follow-up samples (n=629). RVR rates and sustained virologic response (SVR) rates in patients with RVR were compared by Amplicor or TaqMan (HCV RNA <15 IU/mL [undetectable or below the limit of detection] or Undetectable [true negative]) in G2/3 (ACCELERATE) and G1 (NV15942) patients treated with peginterferon alfa-2a (40KD) plus RBV standard dose. cEVR (HCV RNA-negative at wk12) and relapse rates were compared by these two tests in G1 and G2/3 patients in NV15942. BL viral loads were compared by Amplicor Monitor v2.0 and TaqMan in G2/3 patients in ACCELERATE.

Results: RVR and SVR rates were similar when RVR was defined as <50 IU/mL or <15 IU/mL regardless of genotype (Table). RVR rates were slightly lower when defined as HCV RNA undetectable by TaqMan. cEVR rates were similar when cEVR was defined as <50 IU/mL or <15 IU/mL. Relapse rates were lowest when TaqMan undetectable cut-off was utilized to determine EOT response. BL viral loads were well correlated between the two tests. Conclusions: A detection limit of <15 IU/mL by TaqMan serves as a reasonable definition of RVR and cEVR, along with <50 IU/mL, for RGT, regardless of genotype. The significance of HCV RNA "undetectable" by TaqMan should be investigated in prospective trials.
1300

**PATIENTS COINFECTED WITH HCV AND HIV WHO ACHIEVE AN RVR (HCV RNA < 50 IU/ML AT WEEK 4) OR CEVR (HCV RNA < 50 IU/ML AT WEEK 12) HAVE SIMILAR RATES OF SVR TO MONOINFECTED PATIENTS TREATED WITH PEGINTERFERON ALFA-2A (40KD) (PEGASYS®) AND RIBAVIRIN (COPEGUS®)**

1Department of Internal Medicine IV, Medical University of Vienna, Vienna, Austria; 2Kaiser Franz Josef Hospital, Vienna, Austria; 3Krankenhaus Hietzing, Vienna, Austria; 4Krankenhaus der Elisabethinen, Linz, Austria; 5Wilhelminenhospital, Vienna, Austria; 6Medical University Graz, Graz, Austria; 7General Hospital, Linz, Austria; 8Krankenhaus Oberndorf, Salzburg, Austria; 9Krankenhaus Rudolfstiftung, Vienna, Austria; 10Roche Austria, Vienna, Austria

**Background:** Patients coinfected with HIV-HCV represent a challenging population to treat. In the APRICOT study coinfect ed patients treated with 180 µg/wk peginterferon alfa-2a (40KD) and 800 mg/d ribavirin achieved an SVR rate of 40% (29% genotype G1; 62% G2/3). These rates compare poorly to those in monoinfected patients. In monoinfected patients serum samples collected at wks 4 and 12 are increasingly being used to guide therapy decisions (response-guided therapy). There are limited data in coinfected patients on whether early treatment responses are also useful to predict rates of SVR and how rates of SVR in early responders compare between monoinfected and coinfected patients.

**Methods:** Patients included in this analysis were all patients from the APRICOT study randomised to 180 µg/wk peginterferon alfa-2a (40KD) and 800 mg/d ribavirin with G1, 2 or 3 HCV. Rates of SVR were determined as a function of response to therapy at wk 4 and 12. RVR was defined as undetectable HCV RNA (<50 IU/ML) at wk 4; complete EVR (cEVR) was defined as non-RVR but undetectable HCV RNA (<50 IU/ML) at wk 12; partial EVR (pEVR) was defined as non-RVR but ≥2 log reduction from baseline in HCV RNA but remaining detectable HCV RNA (>50 IU/ML) at wk 12; SVR was defined as undetectable HCV RNA (<50 IU/ML) 24 wks after the end of therapy.

**Results:** Data from 271 patients were included (Table). Rates of SVR for G1 and G2/3 were greatest in patients achieving an RVR (G1 = 81.8%, G2/3 94.3%), followed by cEVR (G1 = 63.2%; G2/3 69.7%) and then pEVR. Patients not achieving an RVR or cEVR/pEVR had minimal chance of achieving an SVR. Considering only patients with pEVR, rates of achieving SVR were influenced by several baseline and treatment factors indicating that response in this category of patients is heterogeneous.

**Conclusions:** Coinfected patients who achieve an RVR have a similarly high chance as monoinfected patients of achieving an SVR irrespective of genotype. Patients that achieve cEVR also have similarly high rates of SVR as in monoinfected patients. As in monoinfected patients RVR is the strongest predictor for SVR, but in addition achieving a cEVR is also highly predictive of achieving an SVR.

**Background:** The rate and extent of virological response to therapy in patients infected with HCV genotypes (G) 1 or 4 is highly variable. Retrospective analyses show that patients treated with peginterferon alfa-2a (40KD) plus ribavirin (RBV) who achieve an RVR (HCV RNA < 50 IU/ML at wk 4) may achieve an SVR after only 24 wks, while patients with a slower response may benefit from prolonged therapy. This prospective study investigated response-guided therapy of Peg-IFN alfa-2a (40KD) plus RBV in G1 and 4 patients based on RNA level at wk 4 & 12. We aimed to evaluate whether patients with RVR, EVR (HCV RNA < 600 IU/ML) have a higher chance of achieving an SVR.

**Methods:** Treatment-naive G1 and 4 chronic hepatitis C patients were treated with Peg-IFN alfa-2a (40KD) 180 µg/wk plus RBV 1000/1200 mg/day prior to allocation to one of four arms based on RNA tests at wk 4 & 12. At wk 4, patients with an RVR were assigned to a further 20 wks of therapy (Arm D). All other patients continued to receive treatment until wk 12 when RNA was retested. Patients with an EVR were randomized to a total of 48 (Arm A) or 72 wks (Arm B) of treatment. Wk 12 NRs
were offered to continue treatment for a total of 72 wks (Arm C). Treatment was stopped if RNA remained detectable at wk 24. Results: Of the 580 patients screened 510 patients (G1=443; G4=67) received treatment and were evaluable. Of these 121/443 (27.3%) G1 patients and 29/67 (43.3%) G4 patients had an RVR and were allocated to Arm D. RVR was associated with younger age, lower body weight, lower BL viral load, and G4. By multiple logistic regression analysis viral load (high vs. low OR: 0.26 [95% CI:0.16–0.41]) and genotype (1 vs. 4: OR: 0.29 [95% CI:0.16–0.56]), body weight and ALT but not fibrosis were significantly associated with not achieving an RVR. The outcome of patients with RVR is shown in the table. Conclusion: More patients with G4 than with G1 achieved an RVR. Both G1 and G4 patients with RVR achieved high rates of SVR with 24 wks of treatment. These rates are similar to rates of SVR in G1 patients achieving an RVR with 48 wks of therapy. We confirm that a substantial proportion of patients with G4 and G1 benefit from shortening therapy to 24 wks. Here we show that RVR is predictive of SVR in G4 patients and that G4 patients with an RVR have an even greater chance of achieving an SVR compared to G1 patients.

1302 PHASE 1 EVALUATION OF ANTIVIRAL ACTIVITY OF THE NON-NUCLEOSIDE POLYMERASE INHIBITOR, HCV-796, IN COMBINATION WITH DIFFERENT PEGYLATED INTERFERONS IN TREATMENT-NAIVE PATIENTS WITH CHRONIC HCV

Stephen Villano1, Donald Raible2, Dawn Harper2, Priyamvada Chandra2, Linda Bazisotto3, Geraldine Bichier4, ViroPharma Incorporated, Exton, PA; 2Wyeth Research, Collegeville, PA; 3Northwest Kinetics, Tacoma, WA; 4Center for Clinical Trials Research, University of Florida, Gainesville, FL

Background: HCV-796 is an inhibitor of hepatitis C virus (HCV) RNA-dependent RNA polymerase that has demonstrated clinical antiviral activity across multiple HCV genotypes when administered as monotherapy or in combination with pegylated interferon alfa-2b (PEG2b). We further evaluated HCV-796 when administered with pegylated interferon alfa-2a (PEG2a). Methods: Evaluations were performed within a randomized, double-blind, Phase 1 study in adult patients with chronic HCV infection who were naive to therapy. In one group, patients were randomized to receive oral HCV-796 or placebo Q12h for 14 days, and all were to receive PEG2b (1.5 mcg/kg) on day -1 (one day before start of HCV-796/placebo) and day 7. In another group, the design was the same except the PEG therapy was PEG 2a (180 mcg) on day -1 and day 7. In each group 12-16 patients were to receive the active HCV-796 (500 mg Q12h) with one of the PEG therapies. Results: The median baseline HCV RNA level was 6.46±.3 log10 in each group and 71% of patients were infected with HCV genotype 1. For both PEG therapies, combination with HCV-796 reduced plasma HCV RNA levels to a greater extent than either PEG alone. At day 14, the mean reduction in HCV RNA for HCV-796+PEG2b was 3.4 log10 vs. 1.6 log10 for PEG2b alone. The mean reduction for HCV-796+PEG2a was 3.7 log10 vs. 1.1 log10 for PEG2a alone. For both groups, activity differed by HCV genotype. Mean HCV RNA reductions at day 14 for genotype 1 was 2.9 log10 for HCV-796+PEG2b and 3.2 log10 for HCV-796+PEG2a. For genotype non-1 the respective reductions were 4.4 vs. 4.7 log10. Combination of HCV-796 with either PEG2b or PEG2a provides similar antiviral activity across multiple HCV genotypes over 14 days of therapy. Results support clinical studies of more long-term administration of HCV-796 with either PEG therapy.

1303 PEGINTERFERON ALFA-2A AND RIBAVIRIN FOR 12 OR 24 WEEKS IN PATIENTS WITH HCV GENOTYPE 2/3: THE NORDYNAMIC TRIAL

Martin Lagging1, Court Pedersen2, Mads Rauning Buhl3, Martti Färkkilä4, Nina Langeland1, Kristine March2, Johan Westin1, Åsa Alsiö1, Gunnar Norkrans1, Daniel Färkkilä1, Nina Langeland1, Kristine March2, Johan Westin1, Åsa Alsiö1, Gunnar Norkrans1

Background and Aims: Prior trials investigating the efficacy of treatment for less than 24 weeks in HCV genotype 2/3 infected patients have yielded discordant results. The aim of this study was to compare the efficacy of 12 or 24 weeks of combination therapy, as well as to identify patients achieving SVR using liver biopsy evaluation. IP-10 levels, α-interferon concentrations, ribavirin concentrations, and HCV RNA measurement using Roche COBAS TaqMan at baseline, day 3, day 7, day 8, week 4, and week 8. Methods: Three hundred and eighty-two genotype 2/3 infected patients at 31 centers in Denmark, Finland, Norway, and Sweden were randomized at baseline to 12 or 24 weeks of treatment with peginterferon α-2a 180 μg/week plus ribavirin 800 mg/day from February 2004 to November 2005. Results: Twelve weeks of combination therapy was inferior to 24 weeks for patients infected with genotype 2 (SVR rates 56% vs. 82%, p=0.007) and genotype 3 (58% vs. 78%, p=0.001). Likewise, 12 weeks of treatment was inferior for patients with non-significant fibrosis (p=0.024) and bridging fibrosis (p=0.003), and a similar trend was noted for patients with cirrhosis (p=0.078). Multivariate analysis demonstrated that age as well as HCV-RNA levels on day 7 and 29 were independent predictors of SVR following 12 weeks of therapy. For patients <40 years, no significant difference was noted between 12 and 24 weeks of therapy regardless of HCV-RNA level day 29. Similarly, for patients ≥40 years, no significant difference was noted between the treatment arms if both HCV-RNA day 7 was below 1,000 IU/mL and HCV-RNA was undetectable day 29. If both of these two criteria were not met for
patients ≥40 years, 24 weeks of therapy was superior (p<0.0001). Conclusion: Our findings indicate that 12 weeks of combination therapy may be acceptable for subgroups of, not just for all patients infected with HCV genotypes 2 or 3.

Jensen6, Scott Cruickshank11, John Ferraro1, Aurelia Haller1, Richard Duke1, Timothy Rodell1, David Apelian1; 1Clinical Development and Regulatory Affairs, Globelimmuve, Louisville, CO; 2Center for Liver Diseases, University of Miami, Miami, FL; 3Huntington Medical Research Institutes, Pasadena, CA; 4University of Colorado School of Medicine, University of Colorado at Denver Health Sciences Center, Denver, CO; 5Well Medical College of Cornell University, New York, NY; 6University of Chicago, Chicago, IL; 7The Barry S. Levin, MD Department of Transplantation, California Pacific Medical Center, San Francisco, CA; 8Department of Medicine, University of Hawaii, Honolulu, HI; 9Duke Clinical Research Institute, Duke University, Durham, NC; 10Partners AIDS Research Center, Massachusetts General Hospital/Harvard Medical School, Boston, MA; 11Scott Cruickshank and Associates, Inc., Santa Barbara, CA

**PURPOSE**: Evaluation of the efficacy, immunogenicity, and safety of GI-5005 in subjects with chronic HCV infection.

**METHODS**: GI-5005 is a whole heat-inactivated S. cerevisiae immunotherapy expressing HCV NS3 and Core. Subjects with chronic HCV infection who were interferon (IFN) partial responders, relapsers, or treatment naive were eligible. Five weekly subcutaneous (SC) doses of GI-5005 monotherapy over 29 days were followed by two monthly SC GI-5005 doses and 9 months of post-treatment follow-up. Dose groups of 0.05, 0.5, 2.5, 10, and 40 YU (1 YU = 10,000,000 yeast cells) were randomized 3:1 treated:placebo. RESULTS: Dose escalation was completed without a product-related dose limiting toxicity, serious adverse event, or exacerbation of hepatitis (66 subjects total; 6 in 0.05YU, 6 in 0.5YU, 7 in 2.5YU, 12 in 10.0YU, 11 in 20YU, 7 in 40YU, and 17 in placebo). HCV-specific cellular immune responses with broad epitope coverage were observed by ELISPOT assay in 33% of treated subjects (8/24) to date with a dose response for GI-5005, compared to no responses in the placebo group. Statistically significant improvements in ALT levels were observed in treated subjects with a mean maximum decrease from baseline of 29.3% versus 16.9% for placebo (47 treated versus 17 placebo respectively, p=0.02). Three of the 7 (43%) 20YU patients with abnormal ALT at baseline had normalized their ALT after treatment (> 2 consecutive visits WNL) compared to 0 of 29 treated subjects (14%) from the first 4 dose groups combined, and none of the placebo patients. Six subjects of 47 treated overall (13%) achieved a viral load nadir ranging from -0.75 to -1.04 log10 change from baseline with the 2 greatest reductions (2/11 subjects, 18%) observed in the 20YU group (-0.93 log10 and -1.04 log10). In several cases these viral load reductions persisted for months and in one case for the full 9 month post-treatment follow-up period. No HCV RNA reductions in -0.75 log10 to -1 log10 range were observed in the placebo group. CONCLUSIONS: GI-5005 was well tolerated and generated HCV-specific cellular immune responses with associated HCV RNA reductions and ALT normalizations in a subset of patients, which were not observed in the placebo group. These data support further development of GI-5005 in combination with IFN-based standard of care, or as a salvage treatment in patients who are intolerant or who fail IFN-based regimens. Future evaluation of combination of GI-5005 with small molecule inhibitors of HCV replication is also warranted based on its complementary immune mechanism of action.

ASSOCIATION OF PRE-TREATMENT AND ON-TREATMENT FACTORS WITH RAPID VIROLOGIC RESPONSE IN HCV GENOTYPE 1 INFECTED PATIENTS TREATED WITH PEGIFNα-2A/RBV

Maribel Rodriguez-Torres1, Mark Sulikowski2, Raymond T. Chung3, Fayezy Hamzeh4, Donald M. Jensen5; 1Fundacion Gastroenterologia de Diego, Santurce, PR; 2Johns Hopkins University, Baltimore, MD; 3Massachusetts General Hospital, Boston, MA; 4Roche Laboratories, Nutley, NJ; 5University of Chicago, Chicago, IL

Introduction Rapid virologic response (RVR), defined as undetectable serum HCV RNA after 4 weeks of treatment, is associated with likelihood of sustained virologic response. This retrospective analysis assessed the effect of baseline and demographic factors and drug dose/modification during the first 4 weeks of treatment on RVR. Methods Patients in 5 clinical trials who were infected with HCV genotype 1 and randomized to 180 µg/wk pegIFNα-2a/1000-1200 mg/d RBV were included. Baseline factors utilized for multiple logistic regression analyses included age (<40 vs >40 years), gender, race/ethnicity (non-Latino white vs other), BMI (<27 vs >27 kg/m²), baseline ALT quotient (<3 vs >3X ULN), baseline serum HCV RNA (<400,000 vs >400,000 IU/mL) and cirrhotic classification (cirrhotic vs non-cirrhotic). On-treatment factors included average daily exposure to RBV (<13 vs >13 mg/kg/day) and pegIFNα-2a dose reductions (yes vs no). Any factor with p≤0.2 was considered significant. Results Of 1550 treated patients, 234 (15.1%) attained RVR and 1316 (84.9%) did not; 1 (0.4%) and 16 (1.2%), respectively, withdrew for safety reasons, and 0 and 1 (0.1%), respectively, for non-safety reasons. Of these 1550 patients, 1050 (67.7%) were non-Latino whites, 295 (19.0%) were Latino whites, 154 (9.9%) were black, and 51 (3.3%) were Other; 1031 (66.5%) were men; 1112 (71.7%) were >40 years old; 797 (51.4%) had BMI >27 kg/m²; 1184 (76.4%) had ALT quotient >3X ULN; 1346 (86.8%) had serum HCV RNA >400,000 U/mL; and 239 (16.4%) were cirrhotic. Multiple logistic regression analysis showed that white non-Latino race (OR 1.48; 95% CI 1.04-2.12, p=.031), age ≤40 years (OR 1.63; 95% CI 1.27-2.26, p<.0035), baseline ALT quotient >3X ULN (OR 1.96; 95% CI 1.40-2.76, p<.0001), baseline serum HCV RNA >400,000 IU/mL (OR 8.67; 95% CI 6.13-12.37, p<.0001), cirrhotic status at baseline (OR 1.63; 95% CI 1.01-2.64, p=.0444), male sex (OR 1.37; 95% CI 0.98-1.91, p=.0687) and BMI ≤27 kg/m² (OR 1.37; 95% CI 0.99-1.91, p=.0545) were predictive of RVR. After adjusting for significant risk factors, multiple logistic regression analysis showed that average daily RBV >13 mg/kg/day (OR 2.15; 95% CI 1.41-3.37, p<.0004) was a significant predictor of RVR, whereas pegIFNα-2a dose reduction was not. Conclusion RVR in patients infected with HCV genotype 1 was associated with younger age, white race, higher ALT quotient, lower serum HCV RNA, absence of cirrhosis, male sex and lower BMI, and with greater exposure to RBV over the initial 4 weeks. Patients exposed to ≤13 mg/kg/day RBV over the first 4 weeks were less likely to achieve RVR.

TREATMENT OF PEGINTERFERON/RIBAVIRIN NONRESPONDERS WITH DAILY DOSING OF CONSENSUS INTERFERON AND RIBAVIRIN - PRELIMINARY RESULTS OF THE GERMAN CONSENSUS INTERFERON MULTI-CENTER STUDY

Stephan Kaiser1, Wulf Boecker2, Joerg F. Schlaak3, Bettina Lutze1, Birgit Sauter1, Lennart Bissinger1, Christoph Werner4, Holger Hass2, Michael Gregor1; 1Dept. of Medicine I, University Hospital of Tuebingen, Tuebingen, Germany; 2Medicine, Marienhospital, Stuttgart, Germany; 3Medicine, University Hospital of Essen, Essen, Germany; 4Medicine, University Hospital of Mainz, Mainz, Germany

Objective: Current standard treatment with pegylated interferon (PEG IFN) and ribavirin (RBV) in genotype 1 patients shows sustained response rates of 31 – 47%, thus leaving more than half of the patients with a relapse or nonresponse to . Recently improved response rates have been observed in pilot trials using consensus interferon (CIFN) in combination therapy in PEG IFN / RBV nonresponders. Methods: The efficacy of CIFN daily dosing therapy compared to CIFN / RBV in PEG IFN combination treatment nonresponders was evaluated. 400 patients have been included, with 92% having genotype 1. Average weight of patients was 79.3 kg. Patients were either treated with CIFN at 9 ug QD for 16 weeks or with CIFN 27 ug QD for 4 weeks, followed by 12 weeks of CIFN 18 ug QD. Thereafter, treatment was continued in all treatment groups with CIFN at 9 ug QD with weight-based RBV for 32 - 56 weeks, depending when a patient became first PCR negative, ensuring a treatment period for 48 weeks with a negative PCR. Results: Preliminary data show that after the initial 12 weeks of CIFN monotherapy, a primary response with undetectable serum HCV-RNA was observed in 37 % of patients with a prior nonresponse to PEG IFN α2b and in 48% in prior PEG IFN α2a nonresponders (n=189). At the end of treatment, a negative PCR was observed in 34% in PEG IFN α2b nonresponders, and in 48% of PEG IFN α2a nonresponders. The sustained viral response rates [SVR] were 16% and 23% for PEG IFN α2b and PEG α2a nonresponders, respectively (n=143). When response rates were calculated according to the treatment arm used, the SVR for PEG IFN α2b nonresponders were 13% in the CIFN 9 ug arm and 19% in the CIFN high dose arm. For PEG IFN α2a nonresponders the SVR were 19% and 27% for the CIFN 9 ug dose and high dose arms, respectively. The overall tolerability of the CIFN 9 ug regimen was comparable to a standard therapy with pegylated IFN and RBV, while the CIFN 27/18/9 ug regimen was less tolerable during the high dose induction period. However, drop out rates were not different between the two dosing regimens. Conclusions: CIFN daily dosing / induction therapy together with subsequent RBV combination therapy thus shows promising response rates in previous PEG IFN combination therapy non-responders. Especially PEG IFN α2a nonresponders appear to have a benefit from CIFN QD retreatment. It is concluded that CIFN may be an effective treatment modality for this difficult-to-treat patient group.

PF-03491390 inhibits liver fibrosis in patients with chronic hepatitis C virus infection via suppression of pro-apoptotic caspase-activation.

Gary Burgess1, Peter Colman1, Emanuel Engmann1, Heike Bantel6, Paresh N. Soni2; 1Pfizer Ltd, Sandwich, United Kingdom; 2Department of Gastroenterology, Hepatology and Endocrinology, Hanover Medical School, Hanover, Germany; 3Pfizer Ltd, New London, CT

Background: In patients with chronic HCV infection, the pan-caspase inhibitor, PF-03491390 minimises hepatocellular damage, as reflected by reductions in elevated ALT and AST levels. As caspase activation plays a pivotal role in inflammatory and fibrotic liver injury in HCV-infection, we investigated caspase activation and a range of inflammatory and fibrotic serum biomarkers during therapy with this agent. Methods: 204 patients with chronic HCV infection and liver fibrosis were randomized to receive placebo or PF-03491390 5 mg, 25 mg, or 50 mg orally twice daily for 12 weeks in a placebo-controlled, double-blind, parallel-group study. If ALT and AST levels remained elevated at Week 10, the dose of study drug was doubled to Week 12. Changes in serum markers of inflammation, fibrosis and apoptosis are reported. Results: At Week 12, compared with placebo, PF-03491390 therapy was associated with decreases in serum levels of transforming growth factor (TGF) β1, α-2 macroglobulin, caspase-mediated cytokeratin-18 fragments (M30-Antigen), active caspases 3/7 and α-fetoprotein. PF-03491390 therapy was also associated with increases in serum levels of haptoglobin and Fas ligand, at Week 12, compared with placebo. PF-03491390 therapy had no apparent impact on serum levels of the other measured biomarkers (Table 1). Conclusions: In patients with chronic HCV infection, 12 weeks of PF-03491390 therapy appears to inhibit liver inflammation and fibrosis via suppression of pro-apoptotic caspase-activation. Long-term studies are required to assess the mechanism of action and effects of PF-03491390 in patients with liver fibrosis.

Table 1: Median absolute change of serum markers of inflammation, fibrosis and apoptosis from baseline at Week 12

PF-03491390 differentiates of early virologic response (EVR) into RVR, complete EVR (CEVR) and partial EVR (PEVR) allows for a more precise prediction of SVR in HCV genotype 1 patients treated with peginterferon alfa-2A (40KD) (Pegasys®) and ribavirin (Copegus®).

Patrick Marcellin1, Donald M. Jensen2, Stephanos J. Hadziyannis3, Peter Ferenci4; 1Centre de Recherches Claude Bernard sur les Hépatites Virales, Hôpital Beaujon, Clichy, France; 2Section of Hepatology, St. Luke’s Medical Center, Chicago, IL; 3Henry Dunant Hospital, Athens, Greece; 4Department of Internal Medicine IV, Medical University of Vienna, Vienna, Austria

Background: Early on-treatment responses in HCV RNA at wks 4 & 12 post initiation of therapy are increasingly being used to predict those pts likely to achieve an SVR. Pts achieving an RVR (HCV RNA <50 IU/mL at wk 4 and maintained at wk 12) have a high rate of SVR irrespective of genotype. The standard definition of an early virologic response (EVR) had been defined as pts at wk 12 achieving either an undetectable HCV RNA (<50 IU/mL) or a ≥2 log drop in HCV RNA but still detectable. However, rates of SVR in pts achieving an EVR by this definition are heterogeneous. By further subdividing pts achieving early responses into RVR, complete EVR (cEVR or non-RVR but HCV RNA <50 IU/mL at wk 12) and partial EVR (pEVR or non-RVR but HCV RNA ≥2 log drop in HCV RNA at wk 12 but still detectable) it may be possible to improve the prediction of pts likely to achieve an SVR and may allow for tailoring of treatment duration. Here we performed a retrospective analysis of 2 large, multinational phase III studies of genotype 1 pts treated with peginterferon alfa2a (40KD) in combination with ribavirin (RBV) (Fried et al. NEJM 2002 & Hadziyannis et al. Ann Intern Med 2004). Methods: 569 pts treated for 48 wks with 180 µg/wk peginterferon alfa2a (40KD) and 1000/1200 mg/d RBV were included in the present analysis (ITT). Early responses were divided into 4 mutually exclusive categories as defined above: RVR, cEVR, pEVR and non-EVR (<2 log drop at wk 12). Rates of SVR were then calculated for each category. Results: 16% (90/569) pts were classified as achieving an RVR, 42% (240/569) pts a cEVR, 22% (128/569) pts a pEVR and 20% (111/569) non-EVR. Rates of achieving an SVR in these groups were 87% (78/90) for RVR, complete cEVR, 22% (128/569) pts a pEVR and 20% (111/569) non-EVR pts. Conclusions: Pts achieving an RVR have high rates of SVR and may benefit from shortened treatment duration (24 wks; also see Jensen et al. Hepatol 2006). Pts with a cEVR also have high rates of SVR but should be encouraged to remain on therapy for the standard duration of therapy (48 wks). Pts with a pEVR have lower rates of SVR with the standard 48 wks of therapy and may benefit from intensified treatment (72 wks; also see Sánchez-Tapias et al. Gastroenterol 2006) and pts that are non-EVR at wk 12 have a low chance of achieving an SVR and consideration should be given to change treatment strategy. Early on-treatment virologic responses in HCV RNA are highly predictive of achieving an SVR and subdividing early responses into RVR, cEVR and pEVR allows for a more precise prediction of achieving an SVR.

1309 FINAL RESULTS OF PATIENTS RECEIVING PEG-INTERFERON-ALFA-2A (PEG-IFN) AND RIBAVIRIN (RBV) AFTER A 14-DAY STUDY OF THE HEPATITIS C PROTEASE INHIBITOR TELAPREVIR (VX-950), WITH PEG-IFN
Christine J. Weegink1, Nicole Forestier2,3, Peter L. Jansen1, Stefan Zeuzem2,3, Henk W. Reesink1; 1Academic Medical Center, Amsterdam, Netherlands; 2J.W.Goethe University Hospital, Frankfurt a.M., Germany; 3Saarland University Hospital, Homburg/Saar, Germany

Purpose: Telaprevir (TVR, VX-950) is a highly-selective peptidomimetic inhibitor of the hepatitis C virus (HCV) NS3/4A protease that is designed to block HCV replication. This 14-day study was designed to explore the viral kinetics and safety during dosing with TVR in combination with peginterferon-alfa-2a (Peg-IFN). Here we report the final results of patient status after stopping follow-on standard therapy with Peg-IFN and ribavirin (RBV). Methods: The VX04-950-103 clinical study randomized twenty treatment-naïve patients with chronic genotype 1 hepatitis C infection to three dosing arms. Eight patients received TVR (750 mg as tablets q8h) with Peg-IFN on Days 1 and 8, and eight patients received TVR alone. Four patients received Peg-IFN alone on Days 1 and 8. At the completion of the 14-day study, off-study therapy with Peg-IFN and RBV was offered to all patients. Nineteen of 20 patients began therapy within 5 days of completing the 14-day dosing period. The patient who refused post-study Peg-IFN/RBV was in the TVR-alone group. Results: At week 12 of therapy, all 8 patients in the TVR/Peg-IFN group and 5 of 7 patients in the TVR alone group had undetectable HCV RNA. At week 24, all 15 patients who received TVR had undetectable HCV RNA (<10 IU/mL). Ten patients (6/8 TVR/Peg-IFN and 4/7 TVR alone) chose to stop Peg-IFN/RBV treatment at week 24 and 5 patients chose to continue Peg-IFN/RBV for a total of 48 weeks. All groups were followed for the subsequent 24 weeks. In patients who had received TVR-based therapy for 14 days before starting off-study Peg-IFN/RBV therapy, 7/10 patients treated for a total of 24 weeks and 2/5 patients treated for a total of 48 weeks achieved a sustained viral response (SVR) One patient, treated for 48 weeks, was lost to follow-up. From the group who received Peg-IFN alone before 48 weeks of Peg-IFN/RBV therapy, 1/4 patients achieved SVR. The side effect profile observed during the post-study dosing was consistent with the expected profile of Peg-IFN/RBV therapy. Sequence analysis of the 5 patients who relapsed after TVR-based therapy is in progress. Conclusions: SVR was achieved in 9 of 15 patients treated for 14 days with TVR or TVR/Peg IFN followed by Peg-IFN/RBV therapy for a total of 24 or 48 weeks. These results suggest that TVR-based regimens may increase SVR rates compared to current therapies. Large Phase 2 clinical studies of TVR-based regimens are now ongoing to evaluate this hypothesis and the possibility of shortening the duration of therapy.

1310 RETREATMENT OF HCV GENOTYPE 1 RELAPSE PATIENTS TO PEGINTERFERON/RIBAVIRIN THERAPY WITH AN EXTENDED TREATMENT REGIMEN OF 72 WEEKS WITH CONSENSUS INTERFERON/RIBAVIRIN VERSUS PEGINTERFERON ALFA/RIBAVIRIN
Stephan Kaiser1, Bettina Lutze1, Birgit Sauter1, Lennart Bissinger1, Christoph Werner1, Holger Hass2, Michael Gregor1; 1Dept. of Medicine I, University Hospital of Tuebingen, Tuebingen, Germany; 2Medicine, Marien hospital, Stuttgart, Germany

Objective: Treatment with pegylated interferon and RBV for 48 weeks in naive chronic Hepatitis C patients results in relapse rates of about 20–30%. Recently improved response rates have been observed in treatment-naive patients with a slow viral response as well as in retreatment trials using an extended treatment duration of 72 weeks. However, the optimal retreatment regimen and treatment time remains unclear at present. Methods: The efficacy of CIFN daily dosing + RBV versus PEG IFN a2a + RBV for 72 weeks in patients with a prior relapse to 48 weeks of treatment with PEG IFN + RBV was evaluated. 120 patients with genotype 1. Average weight of patients was 79 kg. Patients were either treated with CIFN at 9 ug QD for 72 weeks or with PEG IFN a2a at 180 ug QW for 72 weeks, both in combination with weight-based RBV. Results: Data show that after the initial 12 weeks a primary response with undetectable serum HCV RNA was observed in 85% of patients in the CIFN QD group and in 81% in the PEG IFN 180 ug group (diff. = n.s.). At the end of treatment at week 72, a negative PCR was observed in 86% in the CIFN group, and in 78% of the PEG IFN 180 ug group (diff. = n.s.). The sustained viral response rates (SVR) were 69% for the CIFN arm and 42% for the PEG IFN a2a arm, respectively (diff. = 0.5), indicating a significantly higher relapse rate in patients being retreated with PEG IFN a2a. No growth factors were used in this study. 5 patients experienced grade III thrombocytopenias, while no grade IV neutropenias or thrombocytopenias were observed. The overall tolerability of the CIFN QD regimen was comparable to the PEG IFN a2a therapy, while the CIFN QD regimen lead to a higher rate of injection site reactions and a slightly higher drop out rate of 19% versus 11% for the PEG IFN a2a group. In contrast, hematologic grade III alterations were higher in the PEG IFN a2a group. Conclusions: Both extended CIFN daily dosing combination therapy and PEG IFN a2a combination therapy for 72 weeks show promising response and SVR rates in previous relapse patients to standard PEG IFN / RBV therapy, while relapse rates are significantly lower in the CIFN retreated patients leading finally to higher SVR rates. Although a significant proportion of patients experienced a second relapse in both treatment regimens after cessation of therapy, the overall sustained response rates are nevertheless promising showing a SVR in up to 70% of patients. It is concluded that extended treatment especially with CIFN in combination with RBV may be an effective treatment modality for this difficult-to-treat patient group.

1311
LONG-TERM LOW DOSE TREATMENT WITH PEGYLATED INTERFERON ALPHA 2B LEADS TO A SIGNIFICANT REDUCTION IN FIBROSIS AND INFLAMMATORY SCORE IN CHRONIC HEPATITIS C NONRESPONDER PATIENTS WITH FIBROSIS OR CIRRHOSIS
Stephan Kaiser1, Bettina Lutze1, Birgit Sauter1, Lennart Bissinger1, Christoph Werner1, Holger Hass2, Michael Gregory1; 1Dept. of Medicine I, University Hospital of Tuebingen, Tuebingen, Germany; 2Medicine, Marienhospital, Stuttgart, Germany

Objective: Treatment with current standard antiviral therapy leaves about 50% of patients without viral clearance with the risk of progression of their liver disease. Recent studies have suggested an antifibrotic effect of low dose interferon treatment. Methods: The efficacy of low dose pegylated interferon alfa 2b with 0.5 ug/kg weekly given for 36 months as monotherapy was evaluated based on histological examination and liver function in 182 patients with chronic HCV, nonresponse to antiviral combination therapy and significant fibrosis / cirrhosis (Ishak staging 3-6) and compared to an observational control group (n=83). Histology was evaluated at baseline, at 18 months of treatment and 6 months after end of treatment. Results: At 18 months therapy an increase in fibrosis score from 3.71 to 4.17 and at 6 months post observation to 4.79 was detectable in the control group (n=78). In the treatment group a decrease from 3.83 at baseline to 2.51 at 18 months and 2.05 at 6 months post therapy was noted (n=167). The necroinflammatory score showed constant levels with 7.89 at baseline, 7.56 at month 18 and 7.73 at 6 months post observation in the control group. In the treatment group the score decreased from 8.61 at baseline to 5.89 at month 18 and then relapsed again to 7.54 post therapy. 61% of patients in the treatment group showed an HCV viral load decline of > 1 log, and 6% had a negative PCR, which however was not maintained for any patient upon cessation of therapy. The drop out rate was 3% and the dose reduction rate was 13%. 22 SAEs were observed, of which 17 were complications of cirrhosis (6 hydropic decompensations, 6 variceal bleeds and 5 HCC development). There was no significant difference of these complications between treatment and observational groups. Conclusions: Low dose therapy with pegylated interferon alfa 2b in patients with HCV and advanced fibrosis or cirrhosis shows a significant and persistent decrease in fibrosis in comparison to a control group. In contrast the also observed significant decrease in the necroinflammatory score is only temporary as long as treatment lasts. As treatment was well tolerated even for patients with cirrhosis, this treatment could evolve as a salvage therapy for patients with advanced liver disease with HCV where standard antiviral therapy has failed.

CORRELATION BETWEEN POLYMORPHISMS OF NS5B AND EARLY CLEARANCE OF HEPATITIS C VIRUS BY PEG-INTERFERON PLUS RIBAVIRIN TREATMENT
Mitsuyasu Nakamura1,2, Hidetsugu Saito2, Naoki Kumagai4, Shinichiro Tada2, Masanori Ikeda2, Nobuyuki Kato3, Toshifumi Hibi2, Soichiro Murai1; 1Internal Medicine, National Defence Medical College, Tokorozawa, Japan; 2Internal medicine, Keio University Scool of Medicine, Tokyo, Japan; 3Molecular Biology, Okayama University School of Medicine and Dentistry, Okayama, Japan; 4Research Center for Liver Diseases, Kitasato, Tokyo, Japan

[Purpose] We previously reported the pilot study indicating relationship between the viral RNA polymerase polymorphisms and the initial decline in viral load induced by IFN-a and ribavirin (RBV) therapy in genotype 1b-related chronic hepatitis C patients. (Kumagai, et al. J Viral hepatit 2004) Substitution of glutamic acid to lysine at the 124th position (E124K) and of isoleucine to valine at the 85th position (I85V) of NS5B was closely associated with viral clearance at 8 weeks of treatment. We have made a prospective study with 69 patients, and analyzed relationship between the NS5B polymorphism and early viral clearance (EVC) at 12 weeks of peg-IFN-a 2b and RBV combination treatment. And we also investigated the mechanism how this polymorphism of NS5B protein affect EVC in vitro using the replicon system. [Methods] The patients received peg-IFN-a 2b and RBV combination therapy for 48 weeks (peg-IFN α2b 1.5 ug/kg a week plus RBV 400-1000 mg daily). HCV RNA was analyzed in pretreatment sera of patients, and correlation between clinical aspects including EVC and HCV polymorphisms in the NS5B region was analyzed. According to the previous report, we analyzed the significance of amino acid substitution at the 85th and 124th of NS5B (V85I, K124M) and its clinical aspect was confirmed by in vitro replicon systems. Identified polymorphisms of NS5B might affect viral replication and finally EVC in peg-IFN + RBV therapy.

EFFECT OF INFlixIMAB ON THE EFFICACY OF PEGINTERFERON ALFA-2B (PEG-2B) PLUS RIBAVIRIN (RBV) THERAPY IN TREATMENT-NAIVE PATIENTS WITH HEPATITIS C GENOTYPE 1 AND HIGH TUMOR NECROSIS FACTOR $\alpha$ (TNF-$\alpha$) LEVELS

Curtis Cooper1, Stephen Shafran2, Susan Greenbloom3, Robert Enns4, John Farley5, Manuela Neuman6, Nabil Abadir7; 1The Ottawa Hospital, Ottawa, ON, Canada; 2University of Alberta, Edmonton, AB, Canada; 3Toronto Digestive Disease Associates, Toronto, ON, Canada; 4St Paul's Hospital, University of British Columbia, Vancouver, BC, Canada; 5Private Practice, Vancouver, BC, Canada; 6University of Toronto, Toronto, ON, Canada; 7Scher- ing-Plough Canada Inc, Pointe Claire, QC, Canada

Background: High levels of TNF-$\alpha$ may contribute to the pathogenesis of hepatitis C virus (HCV) infection. This study evaluated the safety of infliximab in HCV-infected patients and assessed the effect of infliximab induction therapy on early virologic response and sustained virologic response (SVR). This interim analysis reports viral kinetics during the first 12 weeks of treatment. Methods: This was a randomized, prospective, open-label trial conducted at 8 academic and community sites in Canada. Treatment-naive patients with HCV G1 infection and high serum TNF-$\alpha$ levels (>300pg/mL) were randomly assigned to receive either a single pretreatment induction infusion of infliximab (5mg/kg) 7 days before antiviral therapy (Arm A) or no pretreatment (Arm B). All patients received PEG-2b (1.5µg/kg/wk) plus weight-based RBV (800–1400mg/d) for up to 48 weeks. Rapid virologic response (RVR) was defined as undetectable HCV RNA at week 12 between study arms (11/16 Arm A, 6/13 Arm B). All patients received PEG-2b (1.5µg/kg/wk) plus weight-based RBV (800–1400mg/d) for up to 48 weeks. Rapid virologic response (RVR) was defined as undetectable HCV RNA at week 12 <50IU/mL HCV RNA; Amplicor HCV Monitor V2. Results: This analysis is based on the first 29 randomly assigned patients (16 Arm A, 13 Arm B) who received 12 weeks of PEG-2b + RBV; 70% of participants were male. Infliximab was well tolerated, without excessive side effects. More infliximab recipients had advanced (F3) fibrosis (38% vs 15%). At initiation of PEG-2b + RBV, lower mean serum TNF-$\alpha$ levels were observed in patients in Arm A than in Arm B (P<.013). In Arm A, 7/16 (43.8%) patients attained RVR, compared with 4/13 (30.8%) patients in Arm B. By week 8, significantly more patients in Arm A (11/16, 69%) than in Arm B had undetectable HCV RNA than in Arm B (6/13, 46%; P=.024). The number of patients who attained undetectable HCV RNA at week 12 was similar between study arms (11/16 patients in Arm A vs 13 patients in Arm B; P=.183), suggesting that the effect of infliximab may not be sustained past week 8. Conclusion: The anti-TNF-$\alpha$ effect of infliximab on HCV may provide viral decline during the first 8 weeks of HCV therapy. It is unknown whether infliximab treatment before combination PEG-2b + RBV therapy will translate into greater SVR rates.

TREATMENT OF ALCOHOLIC HCV PATIENTS WITH ACETAMINOPHEN 4 G/DAY FOR 5 DAYS DOES NOT AFFECT HEPATIC TESTS COMPARED TO PLACEBO

Jody L. Green1, Kennon Heard1, Gregory M. Bagdan1, Bruna Brands2, Richard C. Dart1; 1Denver Health Rocky Mountain Poison and Drug Center, Denver, CO; 2Centre for Addiction and Mental Health, Toronto, ON, Canada

Retrospective accounts question the safety of maximum labeled daily dose of APAP in alcoholics and in patients with hepatitis C. As part of a larger trial of APAP use in alcoholic patients, we evaluated the effect of APAP on hepatic tests in alcoholic patients who also had hepatitis C virus (HCV) antibody. This was a randomized, double-blind, placebo-controlled trial of recently abstinent alcoholics. Patients were randomized 1:1 to APAP (1g every 4 hr for 4 doses x 5 days) or placebo. Exclusion criteria included a baseline serum APAP > 20 mcg/mL, aspartate aminotransferase (AST) or alanine aminotransferase (ALT) > 200 IU/L, or international normalized ratio (INR) > 1.5. Laboratory measures were obtained at baseline and days 2, 4, 6, and 7. Of 142 patients (74 APAP group, 68 placebo group), 50 subjects were positive for HCV antibody (24 APAP, 26 placebo). Demographics, nutritional status and baseline measures were similar between groups (p>0.05). Baseline ALT was significantly higher in the HCV reactive group (59 ± 38 IU/L) than in the HCV non-reactive group (42 ± 32 IU/L, p<0.05). The ALT in HCV reactive patients was significantly higher throughout the study than HCV non-reactive patients (p<0.05), regardless of treatment group assignment. Of the HCV reactive subjects, the ALT increased during the trial in both groups. However, the ALT was not different between APAP and control groups. The peak ALT mean of HCV reactive subjects was on Day 7 (71 ± 54 IU/L in APAP group, 68 ± 58 in placebo group). Maximum reported ALT was 216 IU/L in APAP group and 246 IU/L in placebo group. Total bilirubin decreased significantly after Day 2, regardless of treatment group assignment. The INR was unaffected in either group. Short-term treatment of alcoholic HCV patients with APAP at the maximum labeled daily dose, 4 g/d, appears safe.

ALT (Mean, Standard Deviation and Range) in Alco- holics with HCV During and Following Maximum Dos- ing of Acetaminophen for 5 Days

FAVORABLE QUALITY OF LIFE (QoL) WITH ALBINTERFERON ALFA-2B PLUS RIBAVIRIN IN GENOTYPE 1, IFN-NAIVE, CHRONIC HEPATITIS C (CHC) PATIENTS

Stephen Pianko1, Eric M. Yoshida2, Stefan Zeuzem3, Yves Benhamou4, Vincent G. Bain5, Erik Pulkstenis6, John G. McHutchison6, G M. Subramanian7; 1Monash University, Melbourne, VIC, Australia; 2University of British Columbia, Vancouver, BC, Canada; 3J.W. Goethe-University Hospital, Frankfurt, Germany; 4Hospital Pitie-Salpetriere, Paris, France; 5University of Alberta, Edmonton, AB, Canada; 6Duke Clinical Research Institute, Durham, NC; 7Human Genome Sciences, Rockville, MD

Background/Aim This Phase 2b, active controlled study evaluated the efficacy and safety of albinterferon alfa-2b (alb-IFN) in IFN-naïve, CHC patients. The effects of alb-IFN on subject quality of life (QoL) and disability days were compared with those of PEG-IFNα-2a (PEG-IFN). Methods 458 patients were randomized and treated in 4 groups: PEG-IFN 180mcg Q1w or one of 3 alb-IFN arms (900mcg Q2w, 1200mcg Q2w or 1200mcg Q4w). The primary efficacy end-point was SVR. SF-36v.2 and the Hospital Anxiety and Depression Scale (HADS) were used to assess subject QoL and anxiety/depression. Subject disability days were evaluated by a number of missed work days or days with impaired activity. Missing data for patient reported outcomes were handled using LOCF (last observation carried forward). Results Based on ITT analysis, SVR rates were comparable (p=NS) across treatment groups. SVR in the 900Q2w was 58.5% and for PEG-IFN was 57.9%. Overall, QoL was similar or favorable for all alb-IFN arms compared to PEG-IFN at all timepoints assessed. At w12 and w24 on treatment, the 900Q2w cohort performed better in all 10 SF-36 domains relative to PEG-IFN. Statistically significant and clinically meaningful differences were observed in mental health (figure), bodily pain, vitality, and social functioning domains. Changes in mental health correlated strongly (r=0.7) with changes in HADS and by w12 post-treatment had recovered to baseline in 67% of 900Q2w subjects and 57% of PEG-IFN subjects. Subjects receiving alb-IFN 900Q2w experienced significantly fewer days of missed work: at w12 and 24, ~5% of 900Q2w subjects missed at least 7 days of work the previous month compared to ~20% for PEG-IFN. Conclusions The alb-IFN 900mcg Q2w dose was associated with the most favorable QoL and fewest missed work days while maintaining efficacy at least comparable to PEG-IFN.

HIGH CHANCE OF CURE IN HCV GENOTYPE 1 PATIENTS WITH A LOW VIRAL LOAD ACHIEVING AN RVR TREATED FOR 24 WKs WITH PEGIFN ALFA-2A (PEGASYS®) PLUS RIBAVIRIN (COPEGUS®): PROSPECTIVE, RANDOMIZED, CONTROLLED STUDY COMPARING 24 AND 48 WEEKS OF TREATMENT

Ming-Lung Yu1,2, Chia-Yen Dai1,3, Jee-Fu Huang4, Li-Po Lee5, Ming-Yen Hsieh1, Chang-Fu Chiu5, Nai-Jen Hou4, Zu-Yau Lin1,2, Shinn-Cheng Chen1,2, Ming-Yuh Hsieh1,2, Liang-Yen Wang1,2, Wen-Yu Chang1,2, Wan-Long Chuang1,2; 1Department of Internal Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan; 2Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; 3Department of Internal Medicine, Kaohsiung Municipal Hsiao-Kang Hospital, Kaohsiung, Taiwan; 4Department of Internal Medicine, Foo Yin Hospital, Pintung, Taiwan; 5Department of Internal Medicine, Paochien Hospital, Pintung, Taiwan

Background: Recommended treatment for patients with HCV genotype 1 (G1) infection is Peg-IFN plus ribavirin (RBV) for 48 wks and 24 wks for HCV G2/3. A rapid virological response (RVR; <50 IU/mL HCV RNA at wk 4) is a strong predictor of sustained virological response (SVR; <50 IU/mL HCV RNA 24 wks after untreated follow-up). SVR rates of >80% with a shorter treatment duration of 12-16 wks peginterferon alfa-2a (40KD) plus RBV in HCV G2/3 pts with an RVR have questioned whether shorter treatment duration can yield high SVR rates for G1 patients with an RVR. Therefore, we determined the efficacy of 24 wks therapy to standard 48 wks treatment in HCV G1 patients with an RVR. Methods: In a controlled, multicenter, open-label study in Taiwan, 200 treatment-naïve G1 patients were randomized (1:1) to 24 wks or 48 wks peginterferon alfa-2a (40KD) 180 µg/wk plus RBV in HCV G2/3 pts with an RVR have questioned whether shorter treatment duration can yield high SVR rates for G1 patients with an RVR. Therefore, we determined the efficacy of 24 wks therapy to standard 48 wks treatment in HCV G1 patients with an RVR. Methods: In a controlled, multicenter, open-label study in Taiwan, 200 treatment-naïve G1 patients were randomized (1:1) to 24 wks or 48 wks peginterferon alfa-2a (40KD) 180 µg/wk plus RBV 1000/1200 mg/d, with a follow-up period of 24 wks. The primary endpoint was an SVR. Results: Baseline (BL) characteristics were similar in the 24 and 48 wk arms. At BL, respectively for the 24 and 48 wk arms, male patients accounted for 57/58% of all patients, with a mean age of 49.7/49.1 years, a mean weight of 65.5/67.5 kg and with 25/19% having a BL diagnosis of advanced hepatic fibrosis (F3/4). BL log HCV RNA (IU/mL) was 5.43 (24 wk) and 5.66 (48 wk). Overall, the 48 wk arm had a significantly lower relapse rate and a higher SVR rate than the 24 wk arm (ITT). Patients with an RVR had a significantly higher SVR rate than patients without an RVR in both treatment arms. For patients with a lower BL viral load (LVL, <400,000 IU/mL) and an RVR at wk 4, the rates of relapse and SVR in the 24 wk arm was comparable to those in the 48 wk arm. MLR analysis in all patients showed that an RVR was the strongest independent factor associated with an SVR, followed by treatment duration, adherence and BL viral load. The 48 wk arm had a significantly higher rate of discontinuation than the 24 wk arm. Conclusion: In this study, high SVR rates (>95%) were seen with both 24 and 48 wks of peginterferon alfa-2a (40KD) plus RBV 1000/1200 mg/d in HCV G1 patients with a LVL and an RVR. BL viral load and an RVR at wk 4 could provide decision-making information for a shorter treatment duration for HCV G1 patients.
1317 TREATMENT OF HEPATITIS C PATIENTS WITH CHILD A AND B CIRRHOSIS WITH CONSENSUS INTERFERON AND RIBAVIRIN IN A LOW ASCENDING DOSING REGIMEN LEADS TO SIGNIFICANT VIRAL ELIMINATION RATES

Stephan Kaiser1, Bettina Lutze1, Birgit Sauter1, Lennart Bissinger1, Christoph Werner1, Holger Hass1, Michael Gregor1; 1Dept. of Medicine, Marienhospital, Stuttgart, Germany; 2Medicine I, University Hospital of Tuebingen, Tuebingen, Germany; 3Medicine, Marienhospital, Stuttgart, Germany

Objective: Antiviral treatment response in patients with chronic hepatitis C and liver cirrhosis is considerably lower than in non-cirrhotic patients and therapy is complicated by high dropout rates, less tolerability of side effects and high rates of hematological complications. Pegylated interferons have shown higher response rates than standard interferons, however, also higher dose-reduction and drop-out rates due to a lower tolerability. Consensus interferon (CIFN) is an interferon with a relatively low half-life, but stronger antiviral potency as shown by high efficacy in nonresponders. Methods: The efficacy of CIFN together with ribavirin (RBV) was evaluated in 120 patients with chronic hepatitis C and cirrhosis Child A and B (average Child score 7.9, maximum MELD score 20) . All patients had histologically proven cirrhosis, elevated ALT values and were viremic, with 79% having genotype 1. Child A patients were treated with CIFN 9 ug TIW for 4 weeks, followed by 9 ug QD for another 4 weeks. Continuing treatment consisted of CIFN 9 ug QD with RBV with a stepwise increase from 400 mg by 200 mg increments at 4 week intervals for a total of another 52 weeks. For Child B patients the two lead-in phases with CIFN monotherapy were extended to 6 weeks each, and the starting dose of RBV was 200mg with an otherwise identical therapy as with Child A patients. Based on tolerability the dosing of RBV was increased to a weight-based dosing for all patients. Results: At 60 weeks therapy an undetectable HCV-RNA was observed in 76% and 47% of Child A and B patients, respectively, with drop out rates of 13% and 27%. Sustained response rates showed a 57% and 27% response for Child A and B, respectively. Due to side effects CIFN had to be dose reduced in 17% and 34%, mainly due to low platelet counts. As growth factors erythropoetin as well as G-CSF was used. 11 patients experienced grade III and 7 patients grade IV thrombocytopenia. Overall tolerability of the CIFN QD regimen was comparable to a standard therapy with pegylated IFN and RBV, while CIFN even as QD treatment resulted in a lower rate of thrombocytopenias. Conclusions: CIFN as a low ascending and finally daily dosing regimen with subsequent escalating RBV shows significant response rates in Child A and B cirrhotic patients. Therapy is also safe, however, a significant portion of patients was unable to even tolerate lower doses of CIFN or RBV. These data suggest that for a subgroup of cirrhotic patients even in stage Child B a combination therapy of CIFN and RBV may lead to viral eradication.

1318 RESULTS OF A PHASE I PLACEBO-CONTROLLED TRIAL IN HEALTHY VOLUNTEERS TO EXAMINE THE SAFETY, TOLERABILITY AND PHARMACOKINETICS OF THE HCV PROTEASE INHIBITOR TMC435350 AFTER SINGLE AND REPEATED DOSING

Rene Verloes1, Khalid Abou Farha2, Andre van Vliet2, Gerben van ‘t Klooster1, Fatima Aharchi1, Kris Marien1, Herman de Kock1, Kenneth Simmen1; 1Tibotec Pharmaceuticals Ltd., Eastgate Village, Little Island, Cork, Ireland; 2PRA International EDS, Stationsweg 163, 9471 GP Zuidlaren, Netherlands

Background: This trial studied the safety, tolerability and plasma pharmacokinetics (PK) of a novel HCV NS3/4A protease inhibitor, TMC435350, after single oral dosing and, in a second step, after 5 days of oral dosing in HCV-negative volunteers. Methods: The single ascending dose (SAD) part was studied under fed conditions using two panels of 9 males or females followed by an investigation on the effects of fasting. In the multiple ascending dose (MAD) part, 4 panels of 9 volunteers were included. Each panel was designed to have 6 subjects receiving TMC435350 solution and 3 subjects receiving placebo. Safety monitoring included physical examination, vital signs, laboratory parameters (haematology, biochemistry, urinalysis), extensive cardiovascular safety (ECGs, and additional biomarkers and echocardiography during the MAD phase), and adverse events. In the SAD study a full PK profile was evaluated up to 72 h post-dose. In the MAD study, a full PK profile was studied on Days 1 and 5, with samples taken up to 72 h post-dose. Results: In the SAD study, oral doses up to 600 mg were well tolerated without attaining any dose-limiting toxicity. The plasma exposure increased in a more than dose proportional fashion. A single dose of 200 mg studied under fasted conditions was well tolerated and yielded comparable exposure to the fed condition. TMC435350 displayed good plasma exposure, with a Tmax of 4.6 hours, which together with a half-life of ~12 hours, supports once daily dosing (qd) in the MAD phase. In that phase, a starting dose of 100 mg was given qd for 5 days. Subsequent doses were 200 mg qd, 200 mg bid and 400 mg qd. All doses of TMC435350 or placebo were well tolerated. There were no grade 3 or 4 adverse events and no clinically relevant changes from baseline on laboratory parameters, vital signs, ECG recordings and echocardiographic evaluations. Minor effects observed were mainly gastrointestinal tract related. Mild, short-lasting erythema was also noted after sun exposure in a few subjects receiving the 200 mg bid dose or placebo. The plasma levels of TMC435350 detected 24 hours after the Day 5 dosing were substantially in excess of the replicon EC50 value for all doses. Conclusions: The data suggest that TMC435350 is safe when given as single doses up to 600 mg and 5 days of dosing up to 400 mg qd. The compound will be further investigated following once-daily administration in HCV patients.
Mean PK parameters after single doses of TMC435350.

1319 ANALYSIS OF RELAPSE RATES IN PEGYLATED INTERFERON AND RIBAVIRIN NON-RESPONDERS TREATED WITH DAILY CONSENSUS INTERFERON AND RIBAVIRIN

Tarek Hassanein1, Reem H. Ghalib2, Nizar N. Zein3, Kenneth D. Rothstein4, Shobha N. Joshi5, Paul Yien Kwo6, Janet Hammond7; 1UCSD Liver Center, University of California, San Diego, San Diego, CA; 2Liver Institute at Methodist Hospital, Dallas, TX; 3The Cleveland Clinic, Cleveland, OH; 4Albert Einstein Center for Liver Disease, Philadelphia, PA; 5Tulane University, New Orleans, LA; 6Indiana University, Indianapolis, IN; 7Valeant Pharmaceuticals North America, Aliso Viejo, CA.

Background: Relapse rates in HCV treatment-naive patients treated with pegIFN/RBV occurs in over 30% of patients. A recent controlled trial of pegIFN/RBV non-responders retreated with a subsequent course of pegIFN/RBV showed a relapse rate of more than 80% and a sustained response in only 3% of patients. While several factors associated with relapse after therapy of naïve patients with pegIFN/RBV have been identified (genotype 1, high viral load, advanced histology, and non-adherence to treatment regimen), predictors of relapse after re-treatment of pegIFN/RBV nonresponders with consensus interferon (CIFN) and RBV remain unknown. Therefore, viral and host factors associated with relapse following 48 weeks of therapy with CIFN/RBV in patients who failed previous pegIFN/RBV treatment were analyzed. Methods: The DIRECT clinical trial is Phase 3, multi-center, and open-label US-based study. 27 genotype 1 patients who had an end-of-treatment response and received daily CIFN (15µg/d) and RBV (1.0-1.2 g/day) were identified for this retrospective analysis. 54% of these patients had a high baseline viral load (VL; ≥850,000 IU/mL), 41% had advanced liver disease/cirrhosis, 44% had evidence of steatosis, and a mean weight of 89kg. 59% of patients had a <2log10 drop in VL during their previous course of pegIFN/RBV therapy. Relapse was defined as VL negative at end of treatment and virus detectable at anytime within the 24-week follow-up period. No adjunctive growth factors were used. Patients had a negative VL if virus was undetectable by both bDNA and TMA assays. Results: The relapse rate in the 27 patients was 59%. The relapse rate in patients with steatosis was 83% compared to 38% in patients who did not have steatosis. Patients that achieved viral negativity by week 12 had the lowest relapse rate (33%), followed by patients that were negative by week 24 (45%). All patients that became viral negative after week 24 relapsed. There was no apparent difference in relapse rates between patients that had a null response (<2log10 drop in VL) versus a partial response (>2log10 drop in VL but detectable HCV RNA) to previous pegIFN/RBV therapy (63% vs. 57%, respectively). Conclusions: Previous pegIFN/RBV non-responders treated with daily CIFN/RBV that achieved viral negativity earlier in the course of treatment were less likely to relapse. The presence of steatosis also appeared to worsen the relapse rates. Previous response to pegIFN/RBV did not appear to have an impact on relapse with retreatment with daily CIFN 15µg/d and RBV. To reduce relapse rates in this population, additional studies evaluating longer duration of CIFN and higher doses of RBV are warranted.

1320 THE EFFECT OF COMPLETE AND PARTIAL RESPONSE AT WEEK 12 ON SUSTAINED Virologic RESPONSE: RESULTS FROM CONTROLLED TRIALS IN NAIVE HCV GENOTYPE 1 PATIENTS TREATED WITH PEGYLATED INTERFERON AND RIBAVIRIN

Mitchell L. Shiffman1, Hank Mansbach2, Janet Hammond2, Mark O’Neill2, 1Hepatology Section, Virginia Commonwealth University Medical Center, Richmond, VA; 2Valeant Pharmaceuticals North America, Aliso Viejo, CA.

Background: Early virologic response (EVR) has been defined as a >2log10 decline in HCV RNA from baseline or undetectable HCV RNA at treatment week 12. However, within the context of EVR are patients who are HCV RNA undetectable at treatment week 12 (complete responders) and a second group that remains HCV RNA positive at week 12 (partial responders). Previous studies have suggested that this latter group has a significantly lower chance of achieving a sustained virologic response (SVR). We, therefore, analyzed a large database of HCV patients who received either pegIFN alfa-2a or -2b along with ribavirin (RBV) and determined the impact of EVR, complete, and partial response on SVR. Methods: A retrospective review of the active control arms (pegIFN/RBV) of two global phase 3, multi-center, randomized, parallel group, double-blind studies in treatment-naive patients was performed. This analysis pooled 392 genotype 1 patients, 204 of whom were treated with pegIFN alfa-2b (1.5mg/kg/wk) and 188 treated with pegIFN alfa-2a (180µg/wk). Both studies used standard weight-based doses of RBV (1.0-1.2 g/day). Week 12 response was categorized as HCV RNA negative (complete responder), >2log10 decline but HCV RNA positive (partial responder), and <2log10 decline in HCV RNA (null responder). Each category of response was evaluated with respect to its ability to achieve SVR. HCV RNA was assessed using the NGI SuperQuant assay (sensitivity to 39 IU/mL). Results: The patient population was 82% Caucasian; mean body weight 81kg; 71% high viral load (>2 million copies), and 34% with advanced fibrosis or cirrhosis (F3-4). At week 12, 56% of patients were complete responders (HCV RNA undetectable), 29% partial responders, and 15% null responders. 335 patients (85%) achieved an EVR and 54% of these patients went on to achieve an SVR. 220 of the EVR patients (66%) were complete responders, and 115 patients (34%) were partial responders. 162 (74%) of complete responders went on to achieve SVR. In contrast, SVR was achieved by only 18 (16%) of partial responders. Only 1 of 57 (2%) null responders achieved an SVR. Conclusions: Approximately 56% of genotype 1 treatment-naive patients treated with pegIFN/RBV became HCV RNA undetectable at week 12, and 74% of these patients achieved SVR. In contrast, only 16% of patients with partial response at week 12 achieved SVR. A study to determine if SVR can be increased in partial responders (those with EVR but HCV RNA positive at week 12) by switching to a more aggressive IFN regimen at week 12 is, therefore, warranted.
1321
COMPARISON OF STANDARD VS EXTENDED PEGYLATED INTERFERON PLUS RIBAVIRIN TREATMENT ACCORDING TO THE TIME OF HCV RNA NEGATIVE IN PATIENTS WITH GENOTYPE 1 AND HIGH VIRAL LOAD
Tatsuya Ide, Teruko Arinaga, Ichiro Miyajima, Kei Ogata, Reiichiro Kuwahara, Yuriko Koga, Kouichirou Kuhara, Ryukichi Kumashiro, Michio Sata; Division of Gastroenterology, Kurume University School of Medicine, Kurume, Japan

Background and aims: Standard duration of pegylated interferon and ribavirin therapy for HCV genotype 1 and high viral load is 48 weeks in Japan. Prior trials investigating the efficacy of longer treatment duration than 48 weeks for HCV genotype 1 demonstrated high sustained virologic response (SVR) rates. Many studies extended the duration of therapy from 48 weeks to 72 weeks. However, in some patients, 72 weeks therapy might be excessive and we should set up the optimal duration of therapy. On the other hand, in patients whose HCV RNA became negative at 4 weeks, SVR can be obtained in almost 100%. These patients maintained HCV RNA negative for 44 weeks. Therefore, we designed extended the therapy which was set up to be HCV RNA negative for 44 weeks and conducted a prospective, randomized, controlled trial investigating whether this extended treatment have higher SVR rate than standard 48 weeks treatment. Methods: 83 genotype 1b and high viral load (>100 KIU/ml, Roche amplicore) patients were randomized at baseline for standard (n=41) or extended (n=42) treatment group. Standard group patients received 48 weeks of treatment. Duration of extended treatment was determined by the time of HCV RNA negative to be HCV RNA negative for 44 weeks (ex. If HCV RNA became negative at week 16, total treatment duration was 60 weeks.). If HCV RNA is positive at week 24, the patient was dropped out of the trial. Results: Two patients in standard group were lost to follow-up. 9 in standard group and 8 in extended group were dropped out because of HCV RNA positive at 24 weeks. 6 in each group discontinued treatment because of the side effects and other reasons. SVR rates were 56.0% (14/25) in standard group versus 81.1% (23/28). Especially, in patients who obtained HCV RNA negative at from week 12 to week 24, SVR rate was significantly higher in extended group (standard vs extended: 35.3% vs 78.9%, P<0.05). Conclusion: Extension of treatment group and 8 in extended group were dropped out because of HCV RNA positive at 24 weeks. 6 in each group discontinued treatment because of the side effects and other reasons. SVR rates were 56.0% (14/25) in standard group versus 81.1% (23/28). Especially, in patients who obtained HCV RNA negative at from week 12 to week 24, SVR rate was significantly higher in extended group (standard vs extended: 35.3% vs 78.9%, P<0.05). Conclusion: Extension of treatment with pegylated interferon plus ribavirin therapy significantly increased the SVR rate in patients with HCV RNA undetectable at 12-24 of treatment.

TOLERABILITY OF LOW-DOSE PEGINTERFERON ALFA-2b IN HEPATITIS C PATIENTS WITH CIRRHOSIS: RESULTS FROM THE COPILOT TRIAL
Manan B. Shah1, Robert S. Brown2, Tera Barski3, Bradley Freilich4, Robert A. Levine5, Nezam H. Afdhal1; 1Gastroenterology and Hepatology, Beth Israel Deaconess Medical Center, Boston, MA; 2Division of Digestive and Liver Diseases, Columbia-Presbyterian Medical Center, New York, NY; 3SUNY Upstate Medical University, Syracuse, NY; 4Kansas City Gastroenterology, Kansas City, MO

INTRODUCTION: Quality of life (QOL) is critical for the utilization of long term maintenance therapies. The aims of this study were to evaluate baseline QOL in patients with advanced fibrosis and to evaluate changes with Peginterferon alfa-2b (PEG-IFN) vs. Colchicine (COLC). RATIONALE: Given side effects of standard doses of PEG-IFN, it is unclear whether lower-dose maintenance therapy would improve or impair QOL. METHODS: 475 patients with advanced Hepatitis C refractory to conventional treatment with Interferon and/or Ribavirin were randomized to receive 0.5µg/kg PEG-IFN alfa 2b weekly vs. COLC 0.6mg PO BID. QOL was assessed by administering the Medical Outcome Trust’s SF-36© survey annually throughout the study. Responses were scored using the norm-based scoring approach, where 50 is the mean for the general population and 10 is the standard deviation. RESULTS: Mental Component Summary (MCS) scores and Physical Component Summary (PCS) scores were calculated for each of the two groups at baseline, 48-weeks, and 96-weeks. Mean values are reported in Table 1. All demographics including age, gender, duration of disease, histology, viral load, biochemical tests, and Child Pugh classification were comparable between the 2 groups. Mean MCS and PCS scores were not significantly different between the study groups at baseline. QOL was relatively stable in the groups with no statistically significant change between baseline and week 96. Mixed procedure analysis revealed a statistically significant effect of treatment assignment only on MCS score (p = 0.02) at week 48 in the COLC group, and values returned to baseline by week 96. The actual difference in score was a modest 4-point reduction in MCS. There was no significant effect of treatment assignment on QOL over time (p = 0.16) in either group. CONCLUSION: Surprisingly, cirrhotic patients were not more than 1 SD below the normal population in either MCS or PCS at baseline. Treatment with low-dose PEG-IFN did not adversely affect QOL over a 2-year period in patients staying on therapy, suggesting that it can be tolerated as a maintenance therapy.

Introduction: Consensus interferon (CIFN) is a synthetic type 1 interferon with enhanced in vitro activity compared to conventional IFN-alfa (IFNa). In the prospective, randomized multicenter Peglntron-Against-Consensus-Trial (PACT), the efficacy and safety of daily CIFN-treatment and ribavirin is compared to Peglnterferon (PegIFN) alfa2b plus ribavirin in genotype 2 and 3 patients. Methods: 262 patients with chronic HCV infection and genotype 2 or 3 were randomly assigned to treatment with peg-IFNa2b (1.5 mcg/kg body weight once weekly, group A) or 9 mcg qd CIFN (group B) for 24 weeks. 194 patients received weight based ribavirin doses, however due to a later protocol amendment, 68 patients received a fixed ribavirin dose of 800 mg qd. Follow up was 24 weeks. Results: There were no significant differences in patient baseline characteristics between both treatment groups concerning age, gender, genotype and viral load. No significant differences were detected between both treatments at end of therapy (EoT) and for sustained virological response (SVR) rates in the intent to treat (ITT) and the per protocol (PP) analysis (ITT: 82% vs. 75% at EoT and 67% vs. 65% SVR; PP: 95% vs. 95% at EoT and 84 vs. 90% SVR). However, the CIFN group displayed a significantly lower relapse rate than group A (3% vs. 9%, p = 0.042) resulting in a slightly higher SVR rate in group B in the PP analysis. Furthermore, no difference in the treatment outcome was found between weight based or fixed ribavirin dose regimens. Treatment was well tolerated in both treatment groups, despite more dose modifications for leucopenia in group B (9% vs. 3%, p = 0.015) without an increased discontinuation rate. Conclusions: In treatment-naive patients with chronic hepatitis C and genotype 2 or 3, daily treatment with CIFN combined with ribavirin has similar antiviral efficacy and safety profile as weight adjusted PegIFNa2b.

Correlation Between Liver Biopsy and FibroSURE during Screening for a Phase II Study to Assess the Antifibrotic Activity of Farglitazar in Chronic Hepatitis C Infection

Keyur Patel1, John G. McHutchison1, Zachary D. Goodman2, Dickens Theodore3, Alison Webster4, Margaret Schultz5, Britt Stancil6, Martin Gardlan7, Stephen Gardner8, 1Gastroenterology, Duke Clinical Research Institute and Duke University Medical Center, Durham, NC; 2Armed Forces Institute of Pathology, Washington, DC; 3GlaxoSmithKline, Research Triangle Park, NC

Background: Non-invasive biomarkers have been proposed as an alternative to liver biopsy for initial staging and assessing changes in fibrosis with therapy in chronic hepatitis C (CHC) patients. Our aim was to assess the utility of the FibroSURE panel in staging fibrosis during screening for enrollment into a multicenter phase II, placebo-controlled, antifibrotic study of a PPARγ agonist (Farglitazar) in CHC infection. Methods: 482 adult CHC non-responders with compensated liver disease had a screening biopsy, and FibroSURE (FS) assay obtained through a central laboratory. Liver biopsy assessment for Ishak staging was performed independently by a single central histopathologist; subjects with Ishak stages 2-4 were subsequently randomized into the study. Screening data were analyzed to determine the accuracy of FS for predicting Ishak fibrosis stage. Results: CHC patients were mostly Caucasians (363/482, 75%), male (297/482, 62%) and with a mean age 52 ± 6.7 yrs. Mean biopsy length was 22.6 ± 11.4 mm. Overall Spearman correlation for Ishak stage and FS, rs = 0.38 (CI, 0.31 – 0.47; p<0.0001); weighted Kappa = 0.15 (CI, 0.11 – 0.19; p<0.0001). FS demonstrated good sensitivity but relatively poor performance for the detection of moderate-to-severe stage (F3-F6) disease [AUC=0.69]. For FS detection of cirrhosis (F5-F6), AUC=0.73, rs=0.25 (95% CI, 0.16 – 0.34). For FS index scores 0.32–0.58 that predicted stage F2-F3 disease, biopsy indicated F0-F1=53/134 (40%), F2-F3=72/134 (54%), and F4-F6 = 9/134 (7%). Conclusions: Non-invasive serum biomarkers such as FibroSURE demonstrate good performance for exclusion of significant disease. However, their utility in differentiation of moderate stage disease is relatively poor, and this may limit their ability to accurately follow changes in fibrosis stage with treatment. This will be further evaluated based on follow-up biopsies at the end-of-treatment in this study.

A 52 Week Multi-Centre, Randomized, Double-Blind Placebo-Controlled Trial Evaluating the Efficacy and Safety of Glycyrrhizin in Patients with Chronic Hepatitis C Not Responding to IFNα or Peg-IFN Plus Ribavirin Therapy

Michael P. Manns2, Igor G. Bakulin2, Natalia P. Blokhina2, Nina I. Khomutianskaia, Heiner Wedemeyer, Tania Roskams2, Hans P. Dienes, Masato Hasebe, Julian V. Platon1, Fabio Baschiera1, 1CEE, PharmaPart AG, Thalwil, Switzerland; 2Gastroenterology and Hepatology, Hannover Medical School, Hanover, Germany; 3Military Therapy, Moscow City Hospital No. 29, Moscow, Russian Federation; 4Moscow Hepatology Center, Moscow Clinical Hospital for Infectious Diseases No. 1, Moscow, Russian Federation; 5Infectious Diseases, Lugas Medical University, Lugansk, Ukraine; 6Department of Morphology and Molecular Pathology, University Hospitals Leuven, Leuven, Belgium; 7Department of Pathology, University Hospital of Cologne, Cologne, Germany; 8Development & Planning Department, Minophagen Pharmaceutical Co., Ltd, Tokyo, Japan; 9Clinical Operations, PharmaPart AG, Thalwil, Switzerland

Background: A significant number of patients with chronic hepatitis C genotype 1 fail to respond to the standard therapy of Peg-IFN-α plus RBV, or cannot be treated for various reasons. There are no options for non-responders to previous standard therapies. Glycyrrhizin (GL) is used in Japan for more than 20 years to treat such cases (SNMC, Minophagen). Studies in non-Asian patients are missing. Objectives: Confirm efficacy (based on ALT and histology) and safety of GL in non-responders to combination therapy. Methods: The trial consists of 2 phases (12 plus 40 weeks). Phase 1 is a randomized, double-blind, placebo-controlled, parallel group comparison of i.v. injections of GL (200 mg glycyr rhizic acid), administered intravenously 5x/ week, or 3x/ week placebo, for 12 weeks. The following phase 2 is a randomized, open comparison of GL 200 mg administered iv 5x/ week versus 3x/ week, for 40 weeks (no placebo for ethical reasons). Adaptive design plan and 2 primary efficacy endpoints: 1 - proportion of patients with ≥ 50% ALT reduction after 12 weeks, and 2 - proportion of patients (≥60%) with improved necroinflammation score after 52 weeks. Inclusion criteria: pos. HCV-RNA, non-Asian, no active ALT, liver biopsy at entry or performed within 6 months. In this study were enrolled 374 patients from 2002 to 2004, [5x/week GL, 3x/week GL, and placebo with N= 123, 127, and 129, respectively], carrying genotype type 1 in 73 % of cases. Baselines (mean, SD): ALT 77 ±49 IU/L, necroinflammation score 7.6 ± 2.5, fibrosis score 3.1 (±1.8). Results: The rate of ALT reduction ≥50% after 12 weeks was significantly higher with 5x/week GL (30%, p = 0.000003) and 3x/week GL (32%, p = 0.000001) compared to placebo (6%). Significant ALT (mean, 95% CI) decrease under active treatment (-33 % -40 to -25) and (-27 % -33 to -21) respectively, but not under placebo (1 %, -8 to +10). Based on evaluable biopsies taken within 6 months before randomization and at the end of the 52 week treatment (N=249 patients) the rate of improvement, defined as at least 1 point scoring difference, in the necroinflammation reached 45% after 52 weeks of treatment, and remained stable in 17%, i.e. no deterioration in 62%. Despite these positive results the second formal primary endpoint (>60% of patients with improved necroinflammation) could not be reached. 4.2% of patients dropped-out for treatment related AEs. Favourable results were also seen in secondary endpoints, including quality of life. Conclusion: GL appears to be effective and well tolerated in the treatment of chronic hepatitis C not responding to IFNα or Peg-IFN plus RBV therapy.
1327
COMPARISON OF PEGINTERFERON ALFA-2A AND RIBAVIRIN FOR 12 OR 24 WEEKS IN PATIENTS WITH HCV GENOTYPE 2 OR 3: THE CLEO TRIAL

Fabrizio Mecenate1, Giuseppe Barbaro2, Adriano Pellicelli3, Angelo Barlattani4, Ettore Mazzoni5, Maria Elena Bonaventura6, Mario Romano7, Lorenzo Nosotti8, Pasquale Arcuri9, Antonio Picardi9, Giorgio Barbarini10, Fabrizio Soccorsi11; 1Medicine, Villa Betania Hospital, Rome, Italy; 2Policlinico Umberto I University of Rome, Rome, Italy; 3Hepatology, S. Camillo Forlanini Hospital, Rome, Italy; 4Hepatology, San Camillo De Lellis Hospital, Rieti, Italy; 5Hepatology, Policlinico Casilino, Rome, Italy; 6Malattie Infettive, IRCCS San Matteo Hospital, Pavia, Italy; 7Hepatology, Campus Biomedico University, Rome, Italy; 8Hepatology, S Camillo Forlanini Hospital, Rome, Italy; 9Hepatology, S. Camillo Forlanini Hospital, Rome, Italy; 10Hepatology, IRCCS S. Giovanni Hospital, Rome, Italy; 11Hepatology, S Camillo Forlanini Hospital, Rome, Italy

Background: In chronic hepatitis C (CHC) patients with genotype 2 or 3, 24 weeks treatment with peg-interferon and ribavirin induces a sustained virological response (SVR) in about 80% of the cases. Recent trials have shown that a similar response rate may be obtained with a shorter treatment period (12 or 16 weeks), especially in patients with rapid virologic response (RVR). Endpoints Primary endpoint of the study was to assess whether 12 week treatment with peg-interferon and ribavirin is as efficacious as 24 week treatment in inducing a SVR in CHC patients with genotype 2 or 3. Secondary endpoint was the rate of relapsers among groups. Methods We performed a multicenter, prospective, randomized trial on 180 historically confirmed CHC patients with genotype 2 or 3 enrolled in 11 italian centers. All patients were treated with peg-interferon alpha2a (180 mcg/week) and ribavirine (800-1200mg/day). After 4 weeks of treatment, the patients with HCV-RNA <600 UI/ml (RVR) were randomized either to 12 weeks (Group A1; n=60) or to 24 weeks (Group A2; n=60) of combination therapy in a 1:1 ratio. The patients without RVR continued standard 24 weeks combination therapy (Group B n=60). In all groups of patients HCV-RNA was checked 12 and 24 weeks after the end of therapy. Results: At the end of the study period SVR was observed in 74% of patients of Group A1, in 84% of patients of Group A2 and in 54% of patients of Group B (P<0.05 vs Groups A1 and A2). Relapsers rate at the end of the study period was 3% in Group A1, 2% in Group A2 and 6% in Group B. Logistic regression analysis showed that baseline HCV-RNA< 1 million/UL (OR: 3.5; P<0.001), a baseline histological inflammation score <7 (OR:2.5; P<0.001), a fibrosis score <2 (OR: 3.3; P<0.001) and a RVR <4 week (OR: 3.5; P<0.001) were the strongest covariates predictive of SVR. Conclusions: In CHC patients with genotype 2 or 3, 12 week combination therapy is as efficacious as 24 week therapy. A RVR is an independent covariate predictive of SVR along with low baseline HCV levels and a low baseline histological inflammation and fibrosis score without significant differences in the rate of relapsers.

Disclosures: The following people have nothing to disclose: Fabrizio Mecenate, Giuseppe Barbaro, Adriano Pellicelli, Angelo Barlattani, Ettore Mazzoni, Maria Elena Bonaventura, Mario Romano, Lorenzo Nosotti, Pasquale Arcuri, Antonio Picardi, Giorgio Barbarini, Fabrizio Soccorsi.

INTERFERON THERAPY PREEMPTIVE PARTIAL SPLENIC EMBOLIZATION FOR HEPATITIS C PATIENTS WITH THROMBOCYTOPENIA

Hiroki Tahara1,2, Yasushi Shimada1,2, Hiroki Tojima1,2, Tomoyuki Hirokawa2, Tatsuya Oyama2, Katsuhiko Horiiuchit, Atsushi Naganuma2, Hirotaka Arata2, Hitoshi Takagi2; 1Gastroenterology, Ota general hospital, Ota, Japan; 2Medicine and Molecular Science, Gunma University Graduate School of Medicine, Maebashi, Japan

INTRODUCTION: Interferon therapy for advanced chronic hepatitis C patients (CH-C) is often difficult because of accompanied thrombocytopenia with hypersplenism. Partial splenic embolization (PSE) is one of the treatments for portal hypertension and hypersplenism. We have introduced PSE to increase platelet count for IFN therapy in CH-C. AIMS & METHODS: The aim of this study was to reveal the efficacy and safeness of PSE before IFN therapy. Subjects were 30 patients (M/F: 13/17; mean age: 57.5) with chronic hepatitis who could not be allowed to have IFN therapy because of thrombocytopenia, platelet count less than 70 thousand /ml, with hypersplenism. We underwent PSE to them before IFN therapy between October 2003 and March 2007. Liver fibrosis grade F1/F2/F3/F4: unknown: 0/2/16/5/7, HCV RNA genotype 1b/2a/2b: 15/11/4, HCV viral load is 989.3±995.8(23-5000) KIU/ml. 25 cases were treated by PEG-IFNα2b+Ribavirin, 3 were IFNα2b+Ribavirin and 2 were PEG-IFNα2a, respectively. RESULTS: Mean rate of embolized-volume of the spleen is 71.7% on CT volumetry. At 2 weeks after PSE, platelet count increased from 7.0±1.9×10⁴/µl to 17.9±5.9×10⁴/µl(P<0.001). WBC count increased from 3526.2±1050.7/µl to 5326.4±1050.7/µl(P<0.001). Hb, T-Bil, Alb, ALT and AST did not change significantly. As for the adverse events by PSE, fever and abdominal pain appeared in all the patients, pleural effusion in 2 cases, ascites in 1 case. No severe complications such as splenic abscess, splenic rupture nor sepsis were observed and all patients could start IFN therapy after PSE. The waiting period after PSE to IFN therapy is 24.2 days. 10 cases are still on treatment. IFN therapy was discontinued because of neutropenia in 2 cases, and strong fatigue in 1 case, but thrombocytopenia was not the reason for IFN discontinuation. Up to now a sustained viral response was obtained for clinical efficacy in 5 of the 16 cases (31%). CONCLUSION: Based on this study, we conclude that PSE is effective to improve thrombocytopenia in patients with CH-C and enable them to have IFN therapy safely.

1329 VIRAL KINETICS OF HCV GENOTYPE 4 DURING PEGYLATED INTERFERON ALPHA 2A – RIBAVIRIN THERAPY

Moutaz F. Derbala1,2, Nazeeth Z. El Dweik1, Saad R. Al Kaabi1, Ajayeb D. Al Marri1, Abdel Bari Bener4, Fatah Shebat2, Aliaa M. Amer5, Mohammed T. Butt4, Rafie Yakooobi1, Muneera Al Mohanadi2, Mooza Al Khini3; 1Gastroenterology and Hepatology, Hamad Medical Corporation, Doha, Qatar; 2Medicine, Weill Cornell Medical College, Doha, Qatar; 3Laboratory Medicine and Pathology-Immunology Section, Hamad Medical Corporation, Doha, Qatar; 4Medical Statistics and Epidemiology, Hamad Medical Corporation, Doha, Qatar; 5Epidemiology and Preventive Medicine, University of Maryland, School of Medicine, Baltimore, MD; 4Laboratory Medicine and Pathology-Haematology Section, Hamad Medical Corporation, Doha, Qatar

Background: Kinetics of Hepatitis C virus (HCV) during pegylated interferon (PEG-IFN) and early monitoring of viral decline were recently described to predict treatment outcomes and in turn reduce the course of treatment, adverse effects and cost. There is limited information on the viral dynamics of HCV-4.

Aim: To follow the HCV-RNA kinetics during Peg-IFN-α2a and Ribavirin therapy and the best time for predicting SVR in genotype 4 patients. Methods: Serum HCV-RNA levels before initial dosing, 24h later then at weeks 1, 4, 12, 24, 48 and 72 were assessed in 84 HCV genotype 4 patients treated weekly by PEG-IFN alpha2a 180microgram and daily Ribavirin(1000-1200mg). Results: At the end of treatment, out of the 84 treated patients, 19 (22.6%) were non-responders while 65 (77%) showed end of treatment response (ETR). However 9 patients relapsed (9.5%), thus the sustained viral response (SVR) was observed in 57 patients (67.9%). Younger patients were more likely to attain SVR, where the odds of SVR increased by a factor of 0.94 for each year increase in age (95% CI 0.90, 0.99, p=0.019). Although a significant negative correlation between stage of fibrosis and rate of viral decline at week 1 & 4 (p<0.005 & 0.001, respectively) was seen, neither fibrosis stage (X2 =3.4882, p>0.1) nor grade of inflammation (X2= 0.0057, p>0.1) significantly predicted response to treatment. Non-responders had no or only a limited decline at week 1 and week 4, whereas sustained virological responders had a significant decline both at week 1 and week 4.

Area under (ROC) curve revealed that week 12 is better than any other time point in predicting SVR (AUC 0.97; 95% CI 0.94, 1.01), (sensitivity 98.3%; 95% CI 90.7, 99.9), (specificity 88.5%; 95% CI 71.0, 96.0), positive predictive value (PPV) of 94.9% and negative predictive value (NPV) of 95.8%. A drop of more than 1.17 log viral load at week 1 and viral clearance or decline >3log at week 4 were considered as the earliest predictors of SVR. Conclusion: In genotype 4 patients, while failure to achieve an EVR at week 12 predicts non-response, and RVR at week 1 & week 4 98% guaranteed SVR. These findings further re-enforce the value of week 12 in the course of IFN treatment. Genotype 4 patients who show significant viral clearance (>1.17 log viral load) by the first week of treatment and viral clearance >3log by week 4 are expected to show SVR and would therefore be assigned to a shorter drug regimen lasting for 24 weeks. Those unfortunate cases who do not achieve viral clearance by week 1 or week 4 should not be deprived from treatment but rather given more time till week 12 before being classified as non-responders.

1330 EFFECTS OF CHRONIC HCV INFECTION ON HEALTH-RELATED QUALITY OF LIFE AND FATIGUE: THE ROLE OF LIVER FIBROSIS PROGRESSION

Gerlinde Teuber1, Arne Schaefer2, Jasmin Rimpel1, Kathrin Paul1, Christian Keicher2, Michael Scheuren2, Stefan Zeuzem1, Michael R. Kraus2; 1Medizinische Klinik I, Klinikum der Johann Wolfgang Goethe Universität Frankfurt/Main, D-60590 Frankfurt/Main, Germany; 2Medizinische Klinik und Poliklinik II der Universität Würzburg, D-97070 Würzburg, Germany

Background and Aims: Health-related quality of life (HRQoL) is significantly impaired in patients with chronic hepatitis C. However, only few studies have been published investigating the relationship between the stage of liver disease and quality of life and revealed conflicting results. Therefore, we investigated HRQoL and fatigue in patients with chronic hepatitis C virus (HCV) infection in relation to the degree of fibrosis while controlling for the influence of relevant demographic and medical variables. Patients and Methods: HRQoL and fatigue were assessed in a cross-sectional multi-center study including a total of 215 consecutive outpatients (92 women and 123 men, mean age 46.7) with chronic HCV infection using the Medical Outcomes Study 36-item Short-Form Health Survey (SF-36) and the German version of the Fatigue Impact Scale (FIS-D). Applying multiple linear regression analyses, the contribution to the variability of these psychometric scores was evaluated for the degree of fibrosis (Ishak Score) as well as viremia, gender, age, mode of transmission, genotype, and ALT. Results: Concerning HRQoL, there was a strong negative association between the degree of liver fibrosis and the physical SF-36 summary score (p=0.016), mainly due to the subscale “general health” (p=0.046). No such relationship was found with respect to the mental domain of SF-36. These effects were independent of the covariate age, also significantly predicting physical HRQoL (p=0.001). Similarly, the absolute FIS score – including the subscale “physical functioning” (p=0.011) – was significantly increased in patients with advanced fibrosis (p=0.043), indicating a higher burden of fatigue symptoms. A further noticeable finding was the more pronounced impairment of the mental SF-36 summary score (p=0.007) and fatigue (p=0.017) in females. However, the psychometric scores of HRQoL and fatigue were found to be unrelated to viremia, mode of transmission, genotype and ALT levels. Conclusions: The present study suggests a significant association of the physical aspects of both HRQoL (SF-36) and fatigue (FIS-D) with the extent of fibrosis in patients with chronic hepatitis C while viral factors such as viremia and genotype exert no significant effect. Female HCV patients were particularly affected by impaired mental components of HRQoL and fatigue, possibly indicating gender-specific aspects of coping. Our findings stress the need for considering fibrosis stage for the identification and management of HCV patients at risk for reduced physical HRQoL.

1331 RETREATMENT OF TREATMENT EXPERIENCED HCV PATIENTS WITH PEGYLATED INTERFERON ALFA-2A AND THYMOSIN ALPHA-1: POOLED ANALYSIS OF TWO RANDOMIZED CONTROLLED TRIALS

Kenneth E. Sherman1, Stuart C. Gordon2, Rehan Ifikar3, Maribel Rodriguez-Torres4, Vinod K. Rustgi5, Adrian M. Di Bisceglie6; 1Division of Digestive Diseases, Univ. of Cincinnati, Cincinnati, OH; 2Department of Medicine, Henry Ford Medical Center, Detroit, MI; 3Dept. of Medicine, Saint Louis University, St. Louis, MO; 4Fundacion de Investigacion de Diego, Puerto Rico, PR; 5Dept of Medicine, Georgetown Univ., Washington, DC, DC; 6Dept. of Medicine, St. Louis Univ., St. Louis, MO

BACKGROUND: Management of HCV-infected treatment non-responders remains a significant clinical challenge. Early pilot studies suggested that an immunomodulatory peptide, thymosin alpha-1 (TA-1) may play a role in enhanced viral clearance, histologic improvement and sustained viral response (SVR). We performed two parallel randomized controlled trials to evaluate efficacy of TA-1 in this difficult to treat population. METHODS: Both trials had similar designs. Patients were randomized to receive either pegylated interferon alfa 2a 180 mcg (PEG) SQ qwek + TA-1 for 48 weeks, or PEG with placebo TA-1 for 48 weeks. One trial (803) permitted subjects with mild fibrosis through bridging fibrosis (Metavir F1-3) while the other (804) enrolled subjects with more advanced baseline fibrosis (F3 or F4). Each trial planned enrollment of at least 500 subjects with a 1:1 randomization between TA-1 and placebo TA-1. Baseline and post-treatment liver biopsies were obtained. RESULTS: Cumulative enrollment in the two trials was 1061 subjects. Nearly all were genotype 1 (93.5%), and 83% had previously failed treatment with interferon alfa + ribavirin and 17% with interferon alfa alone. HCV RNA viral load at baseline was similar between the two trials and averaged log 6.2 copies/ml. 71% of subjects were male and their mean age was approximately 50 years. By intention-to-treatment analysis (ITT), viral clearance at week 48 occurred in 74/533 (13.9%) of subjects treated with PEG + TA-1 vs. 76/528 (14.4%) in the control arm. SVR was observed in 13 subjects (2.4%) in the active treatment arm and 9 subjects (1.7%) in the placebo arm (not significant). The proportion of patients demonstrating an improvement of Knodell Histologic Activity Score (HAI) by 2 or more points was similar in treatment and control groups. Decreases in circulating CD4 lymphocytes were lower among subjects with more advanced fibrosis who received TA-1 vs those receiving placebo. Treatment emergent toxicities were similar between treatment groups. CONCLUSION: Among treatment experienced subjects with HCV infection, retreatment with PEG + TA-1 resulted in a similar sustained virologic response when compared to use of PEG monotherapy. Studies utilizing PEG, TA-1 and ribavirin are in progress.

1332 U.S. MULTICENTER PILOT STUDY OF DAILY CONSENSUS INTERFERON (INFERGEN) PLUS RIBAVIRIN FOR “DIFFICULT-TO-TREAT” HCV GENOTYPE 1 PATIENTS: TOLERANCE AND ON-THERAPY VIROLOGIC RESPONSE

Samuel B. Hoi1,2, Bashar Agee1,3, Eric Dieperink2,4, Lori Tetrick2, Yngve Falck-Ytter4, Charles A. de Comarmond4, Coleman I. Smith1,2, Daniel McKee12, Anastasios A. Mihos2, William Boyd2, Clark C. Kulig2, Marcos Pedrosa9, Edmund J. Bini10,11, Medicine, VA San Diego Healthcare System, San Diego, CA; 2Medicine, VA Medical Center, Minneapolis, MN; 3Psychiatry, VA Medical Center, Minneapolis, MN; 4Medicine, VA Medical Center, Cleveland, OH; 5Medicine, VA Medical Center, Salisbury, NC; 6Medicine, VA Medical Center, Richmond, VA; 7Medicine, VA Medical Center, New York, NY; 8Gastroenterology, Minnesota Gastroenterology, Minneapolis, MN; 9Gastroenterology, Northland Gastroenterology, Duluth, MN; 10Medicine, University of California, San Diego, San Diego, CA; 11Medicine & Psychiatry, University of Minnesota, Minneapolis, MN

Patients in the U.S. with HCV genotype 1 respond poorly to treatment with pegylated interferon alfa and ribavirin (RBV). Consensus interferon (CIFN; interferon alfacon1) demonstrates enhanced activity in vitro compared with other interferons. Genotype 1 patients may benefit from an interferon with increased activity, more favorable viral kinetics from daily dosing, and a longer duration of therapy. Purpose: To determine the efficacy and safety of daily CIFN+RBV for initial treatment of patients with HCV genotype 1 and other “difficult-to-treat” characteristics. Methods: Patients with HCV genotype 1 were prospectively enrolled in 7 Veterans Affairs (VA) and 2 private medical centers. Patients were randomized to treatment with daily CIFN (15 mcg/d sq) and RBV (1-1.2 gm/d PO) given for (A) 52 weeks, vs (B) 52 to 72 weeks (from time of initial virologic response + 48 wks). Treatment is discontinued if HCV RNA is detectable at wk 24. Results: 64 patients initiated treatment (92% male, 33% African American, 78% VA, 67% high viral load; 59% stage III/IV fibrosis, mean body weight 92.5±2.1 kg). ITT analysis of 64 patients with virologic data through 24 wks indicated that 43 (67%) achieved undetectable viral levels; overall 21 (33%) demonstrated a rapid virologic response (RVR) at 4 wks, 16 (25%) were early virologic responders between 8-12 wks, and 6 (9%) were late virologic responders between 12-24 wks. During treatment 27 (42%) patients required CIFN dose reduction and 18 (28%) required RBV dose reduction. Five patients were discontinued at 24 weeks due to virologic non-response. Overall early discontinuation of treatment before 24 wks occurred in 22/64 (34%) patients (9 due to intolerance; 10 due to noncompliance; 1 due to chest pain; and 2 due to cellulitis). This is comparable with the 32% discontinuation rate reported in a large VA cohort treated with interferon alfa-2b+RBV (J Viral Hep 2006;13:242). Final ETR and SVR data are pending. Conclusions: Patients with hepatitis C genotype 1 and “difficult-to-treat” characteristics treated with daily CIFN+RBV demonstrated a high RVR rate, with 33% virus-negative at 4 wks and 67% virus negative by 24 wks. This compares favorably with RVR rates of 19-22% for genotype 1 patients treated with pegylated interferon alfa-2a and ribavirin (Gastroenterology 2006;130:1086 and 131:451). Although adherence and tolerability are limitations, these data indicate that daily CIFN+RBV for initial treatment of U.S. genotype 1 patients have promise primarily via an enhanced RVR rate. (Supported by Valeant Pharmaceuticals; Veterans Affairs Research Service)
Predicted outcomes after 48wks treatment with PegIFN alfa-2a/RBV in G1

1333
OUTCOMES IN HIV-HCV CO-INFECTED GENOTYPE 1 PATIENTS TREATED WITH PEGINTERFERON ALFA-2A (40KD) PLUS RIBAVIRIN (RBV) 1000/1200 MG/D: PREDICTIONS BASED ON A GENERALIZED ADDITIVE MODEL (GAM)
Francesca Torriani1, Maribel Rodriguez-Torres2, Juergen Rockstroh3, Eric Snoeck4, Karin Jorga5, Douglas T. Dieterich6; 1Division of Infectious Diseases, UCSD Infection Prevention and Clinical Epidemiology Unit, San Diego, CA; 2Fundacion de Investigacion de Diego, Ponce School of Medicine, San Juan, PR; 3Medizinische Klinik I, University of Bonn, Bonn, Germany; 4Exprimo NV, Mechelen, Belgium; 5Roche, Basel, Switzerland; 6Mount Sinai School of Medicine, New York, NY

Background: It is now well established that HCV genotype 1 (G1) mono-infected patients benefit from starting RBV at a dose of 1000/1200 mg/d instead of the lower 800 mg/d dose used in earlier studies. In the APRICOT trial, HIV-HCV co-infected patients were treated with peginterferon alpha-2a (40KD) plus RBV 800 mg/d for 48 weeks. The 800 mg/d dose of RBV was selected to minimize hematologic toxicity and the potential for drug–drug interactions with nucleoside reverse transcriptase inhibitors. In APRICOT, the rate of SVR was 40% overall and 29% in G1 patients. We modeled the probability of SVR and anemia in co-infected G1 patients and predicted the outcomes for treatment with RBV 1000/1200 mg/d. Methods: Binary data from 176 G1 patients in APRICOT were incorporated into an existing generalized additive model (GAM) established with data from 817 mono-infected G1 patients enrolled in two phase III clinical trials. The effect of prognostic factors on SVR and anemia (Hgb <10 g/dL) were analyzed and simulations run with the updated GAM to predict SVR and the incidence of anemia in co-infected G1 patients treated with peginterferon alfa-2a (40KD) plus RBV 1000/1200 mg/d. Uncertainty was quantified by 'bootstrap'ing. Results: After incorporating data from APRICOT, significant predictors of SVR retained in the model included baseline (BL) viral load, RBV dose (mg/kg), age, BL ALT quotient, histological diagnosis (cirrhosis vs no cirrhosis) and HIV status (yes vs no). BL factors predictive of anemia included BL Hgb level, RBV dose (mg/kg), age, sex, HIV status, BL ALT quotient and BL viral load. Use of RBV 1000/1200 mg/d in co-infected G1 patients is predicted to increase the SVR rate by 8% (from 29% to 37%) and the incidence of anemia from 14% to 23% (Table). Conclusions: Our simulations suggest that increasing RBV dose to 1000/1200 mg/d, would improve SVR rates in patients co-infected with HIV and HCV G1. However, higher doses of RBV would also be associated with a higher incidence of anemia. Therefore, Hgb levels should be monitored closely and the RBV doses should be decreased in small decrements to preserve chances for higher end of treatment responses and to prevent relapses.

1334
HEPATIC SOCS3 EXPRESSION IS STRONGLY ASSOCIATED WITH NON-RESPONSE TO IFN TREATMENT IN CHRONIC HCV
Kyung Ah Kim, Wenwu Lin, Ethan Weinberg, Carolina B. Borges, Andrew W. Tai, Yoshitaka Kamegaya, Raymond T. Chung; Gastrointestinal Unit, Department of Medicine, Massachusetts General Hospital, Harvard Medical School, Boston, MA

Background/Aims: The combination of pegylated interferon (IFN) and ribavirin (RBV) is the most effective treatment for chronic hepatitis C (CHC), but response rates vary depending on viral and host factors. We hypothesized that key regulators of the IFN signaling pathway are predictive of treatment outcome. We measured the intrahepatic protein expression of STAT1, SOCS3 and ISG15, each of which play a key role in IFN signaling and are known to be altered in hepatitis C virus (HCV) infection, and correlated their expression with treatment outcome. Methods: 49 unselected patients treated with at least 12 weeks of PegIFN and RBV (36 genotype 1, 13 genotype 2/3) with CHC were analyzed. STAT1, SOCS3 and ISG15 were stained using the immunoperoxidase method on pretreatment liver biopsy samples and quantified by NIH Image J software. Results were expressed as percent area positive. Staining was correlated with either sustained virologic response (responder) or nonresponse/response-relapse (nonresponder). Results: Pretreatment hepatic SOCS3 protein expression was significantly higher in nonresponders than in responders for patients with CHC (21.6±± 2.7 vs 10±±1.3, p<0.001). When compared only among genotype 1 patients, SOCS3 expression remained significantly higher in nonresponders than responders in patients with CHC (23.0±± 2.9 vs 12.6±±1.8, p<0.05). Genotype 1 responders had similar levels of staining as genotype 2/3 responders. There were no clinical, virological and histological factors associated with hepatic SOCS3 expression other than IFN response/nonresponse. The hepatic expression of STAT1 and ISG15 did not differ between nonresponders and responders. Conclusions: Pretreatment intrahepatic SOCS3 levels are correlated with outcomes of interferon-based treatment in patients with chronic HCV. The
finding that SOCS3 levels were comparable among responders irrespective of genotype suggests that SOCS3 may be a more powerful pre-treatment predictor of response than genotype. These data strongly implicate SOCS3 as an important antagonist of the in vivo response to IFN. Prospective validation of SOCS3 as a clinical tool to predict response is warranted.

1335 EUROPEAN LIVER FIBROSIS (ELF) PANEL OF SERUM MARKERS CAN PREDICT CLINICAL OUTCOME IN A COHORT OF PATIENTS FROM ENGLAND WITH MIXED AETIOLOGY CHRONIC LIVER DISEASE

Julie Parkes1,2, Paul Roderick1,2, Scott Harris1, Carol Gough3, Mark Wheatley2, Graeme J. Alexander4, Jane D. Collier5, Christopher P. Day6, David J. Mutimer7, John Ramage8, Alistair Burt9, William M. Rosenberg10; 1Public Health Sciences & Medical Statistics, University of Southampton, Southampton, United Kingdom; 2Liver Group, University of Southampton, Southampton, United Kingdom; 3Wellcome Clinical Research Facility, Southampton General Hospital, Southampton, United Kingdom; 4Department of Medicine, Addenbrooke's Hospital, Cambridge, United Kingdom; 5Department of Gastroenterology, John Radcliffe Hospital, Oxford, United Kingdom; 6SCMS (Gastroenterology & Hepatology), University of Newcastle upon Tyne, Newcastle, United Kingdom; 7Liver Unit, Queen Elizabeth Hospital, Birmingham, United Kingdom; 8Department of Gastroenterology and Hepatology, North Hampshire Hospital, Basingstoke, United Kingdom; 9Clinical and laboratory services, University of Newcastle upon Tyne, Newcastle, United Kingdom

Introduction The performance of non-invasive tests has been evaluated against fibrosis on biopsy but use of clinical outcomes as the reference standard would be ideal. The ELF panel of markers (TIMP1, HA, PIIINP) has been shown to have excellent ability to identify significant fibrosis on biopsy. To evaluate ELF performance in predicting clinical outcomes, the original ELF cohort was followed-up at 8.9 years. Methods: Patients recruited to the ELF study at 6 centres were followed up for liver morbidity and mortality by examination of clinical data. Those lost to follow up were followed up for morbidity by questionnaire to the family practitioner. Primary outcome measure was liver related morbidity or death; secondary outcome was all-cause mortality. Results: 448 patients were followed up after a median of 7.7 years representing 99% of those recruited at 6 sites. Median age at infection (p<0.0001) were associated with accelerated fibrosis rate. Body mass index (BMI) (p= 0.018) and increased time interval to first biopsy (“long-term rate”). Linear regression was used to assess the relationship of demographic variables to fibrosis rate. Linearity of long-term fibrosis change over time was assessed using polynomial regression. Results: Of the 161 paired biopsy patients, 136 had historical information allowing estimation of a long term rate of fibrosis prior to therapy: mean time interval to first biopsy 23.6 years; stages: <1 (17.6%, mean 21.4 yrs), 1-2 (71.3%, mean 24.0 yrs), >2 (11.0%, mean 24.8 yrs); overall fibrosis rate .06545 stages/year with “best fit” statistical analysis revealing non-linearity of the stages (p<0.001). Body mass index (BMI) (p= 0.018) and increased age at infection (p<0.0001) were associated with accelerated rates of fibrosis. The mean interval between biopsy samples was 4.1 years; overall stage increased by just 0.168 stages (8.7% decreased, 67.1% stable, 10.6% increased by 0.5 stage and 13.7% by one stage or more), resulting in an overall short term fibrosis rate of 0.03995 stages/year; BMI

1336 TRACKING THE COURSE OF HEPATITIS C WITH PAIRED BIOPSIES - A CRITICAL ANALYSIS

Maryam Rajablu1, Andrew S. Mugglin2, Kenneth P. Batts3, Coleman I. Smith3,4; 1Internal Medicine, Abbott Northwestern Hospital, Minneapolis, MN; 2Biostatistics, University of Minnesota, Minneapolis, MN; 3Gastroenterology, Abbott Northwestern Hospital, Minneapolis, MN; 4Gastroenterology, Minneapolis, MN; 5Gastroenterology, Abbott Northwestern Hospital, Minneapolis, MN; 6Pathology, Minneapolis, MN; 7Gastrointestinal Pathology, Minneapolis, MN

Purpose: To determine if paired liver biopsies in following the course of patients with hepatitis C is of value. Methods: Blinded histologic re-examination of liver biopsy samples was undertaken from a cohort of 161 chronic hepatitis C patients who had undergone at least two (non-protocol) liver biopsies. Fibrosis was assessed using the Batts/Ludwig 0-4 staging system, with intermediate stages (e.g. 1.5) being used in an attempt to maximize the sensitivity. Grade and other co-morbid conditions were also recorded. The rate of fibrosis (stage/year) was determined both from the paired samples (“short-term rate”) and from the estimated time of infection by hepatitis C (per history) to the first liver biopsy (“long-term rate”). Linear regression was used to assess the relationship of demographic variables to fibrosis rate. Linearity of long-term fibrosis change over time was assessed via polynomial regression. Results: Of the 161 paired biopsy patients, 136 had historical information allowing estimation of a long term rate of fibrosis prior to therapy: mean time interval to first biopsy 23.6 years; stages: <1 (17.6%, mean 21.4 yrs), 1-2 (71.3%, mean 24.0 yrs), >2 (11.0%, mean 24.8 yrs); overall fibrosis rate .06545 stages/year with “best fit” statistical analysis revealing non-linearity of the stages (p<0.001). Body mass index (BMI) (p= 0.018) and increased age at infection (p<0.0001) were associated with accelerated rates of fibrosis. The mean interval between biopsy samples was 4.1 years; overall stage increased by just 0.168 stages (8.7% decreased, 67.1% stable, 10.6% increased by 0.5 stage and 13.7% by one stage or more), resulting in an overall short term fibrosis rate of 0.03995 stages/year; BMI
The mean rate of fibrosis was detected in 123 untreated patients (57.4%), and men and 0.08 ± 0.02 respectively. Progression of fibrosis scores was detected in all treated patients with sustained virologic response. The rate of progression was non-linear in HCV with accelerated disease over time in untreated patients resulting in complications of chronic liver disease, hepatocellular carcinoma and death. Cohort studies and clinical decisions based on single biopsy estimates of disease progression may underestimate the risk of fibrosis progression.

1338
DIAGNOSTIC ACCURACY OF THE APRI FOR THE PREDICTION OF HEPATITIS C-RELATED FIBROSIS: A SYSTEMATIC REVIEW
Abdel Aziz Shaheen, Robert P. Myers; Liver Unit, Department of Medicine, University of Calgary, Calgary, AB, Canada

Background: The development of noninvasive markers of liver fibrosis is a clinical and research priority. The aspartate aminotransferase to platelet ratio index (APRI) is a promising tool with limited expense and widespread availability. Our objective was to systematically review the performance of the APRI in hepatitis C virus (HCV)-infected patients. Methods: An electronic search on Medline, EMBASE, and the Cochrane Library (01/1997-12/2006), supplemented with a manual search, identified studies comparing the APRI with liver biopsy for the assessment of HCV-related fibrosis. Random effects meta-analyses and areas under summary receiver operating characteristic curves (AUC) were examined to characterize APRI accuracy for significant fibrosis (stages 2-4) and cirrhosis. Random effects meta-regression was used to determine the impact of study and patient-related factors on APRI performance. Results: In 22 studies including 4,266 patients (median age, 44 years; 61% male), the prevalence of significant fibrosis and cirrhosis were 47% (range 9-72%) and 15% (range 7-33%), respectively. The summary AUCs of the APRI for these outcomes were 0.76 (95% CI 0.74-0.79) and 0.82 (95% CI 0.79-0.86), respectively. For significant fibrosis, an APRI threshold of 0.5 was 81% sensitive and 50% specific. At a 40% prevalence of significant fibrosis, this threshold had a negative predictive value (NPV) of 80%, but could reduce the necessity of liver biopsy by only 35%. For cirrhosis, a threshold of 1.0 was 76% sensitive and 71% specific. At a 15% cirrhosis prevalence, the NPV of this threshold was 91%. Higher APRI thresholds had sub-optimal positive predictive values except in settings with a high prevalence of cirrhosis. APRI accuracy for significant fibrosis was not affected by the prevalence of advanced fibrosis, or study and biopsy quality. However, the accuracy for cirrhosis was greater in studies including HIV/HCV-coinfected patients. Conclusions: The major strength of the APRI is the exclusion of significant HCV-related fibrosis. Future studies of novel markers should demonstrate improved accuracy and cost-effectiveness compared to this economical and widely available index.

1337
LONG-TERM MORBIDITY AND MORTALITY OF HCV INFECTION: A 25 YEARS FOLLOW-UP
Sanaa Kamal1,2, Imad Nasser1, Samer El Kamary3, Michelle Shardell3, Mohamed Hashem2, Amany Ibrahim2, Ashraf Moutsatsa2, Iman Fathy4,2, Maha Sabhi4,2, Amal Abdel Baky4, Hoda Mansour2,4; 1Liver Disease Center, Harvard Institutes of Medicine, Boston, MA; 2Liver Disease Center, Ain Shams University, Cairo, Egypt; 4International Medicine, University of Maryland, Baltimore, MD; 4Liver Diseases, DIAGSERA, Cairo, Egypt

Background/Aims: The natural history of HCV is highly variable and not well characterized. Most cohort studies have not been well controlled with serial liver biopsies to estimate true disease progression. The aim of this study was to investigate the long-term clinical and histological outcome of a cohort of untreated and treated subjects followed for 25 years with a known onset of acute HCV. Study design/methods: In this retrospective-prospective longitudinal cohort study, archived serial serum samples from 420 subjects with non A-non B acute hepatitis between 1981-1982 were re-screened for HCV (ELISA, PCR). Of the 385 subjects with proven acute HCV, 36 subjects refused enrolment, 45 had confections and were excluded, and 214 were enrolled and prospectively followed. Clinical, virological and HRQOL evaluations were performed. Liver biopsies were either available at entry (n=49) or were performed at enrollment (n=96). Liver biopsies were repeated6-17 years after the initial biopsies in patients considered for treatment. Ishak score and fibrosis progression rates were determined. The clinical end-points were end-stage disease, hepatocellular carcinoma (HCC), liver transplantation or death. Results: The disease duration ranged between 22-25 years. Of the 385 patients with acute hepatitis C, 127 subjects (33%) had spontaneous persistent resolution. At baseline, none of the 214 patients with chronic hepatitis had clinical decompensation, HCC or significant impairment of HRQOL. Eighty-two patients (38%) had history of interferon therapy or were treated during the study. The baseline mean necroinflammatory and fibrosis scores were 2.8±3.9 and 0.5±0.02 respectively. Progression of fibrosis was detected in 123 untreated patients (57.4%), and 18 patients with no response to treatment. The mean rate of fibrosis progression in untreated patients was 0.19±0.08 in men and 0.08±0.01 in women (p=0.05). Improvement in fibrosis scores was detected in all treated patients with sustained virologic response. The rate of progression was non-linear and higher in older patients. During follow-up significant impairment of HRQOL was reported in 63 subjects (29.4%), end-stage disease in 41 (19%), liver transplantation in 23 (10.7%), HCC in 23 (10.7%). Death due to liver-related causes was reported in 23 patients (11%). Conclusion: Disease progression is non-linear in HCV with accelerated disease over time in untreated patients resulting in complications of chronic liver disease, hepatocellular carcinoma and death.
COMPARISON OF REPRODUCIBILITY OF HISTOLOGY, BLOOD TESTS AND FIBROSCAN FOR LIVER FIBROSIS
Paul Cailes1, Jerome Boursier1, Marie Christine Rousselet2, Sophie Michalak2, Frederic Oberli1, Yves Gallois3, Victor De Ledinghen4, Francoise Lunei5, 1Hepatology, University hospital, Angers, France; 2Pathology, University hospital, Angers, France; 3Biochimie, University hospital, Angers, France; 4Hepatology, University hospital, Bordeaux, France; 5Virology, University hospital, Bordeaux, France

Our aim was to compare the reproducibility of histology, blood tests and Fibroscan for liver fibrosis by comparing the intra-method and the inter-method agreements by taking as histological reference the reading by a senior expert pathologist. Several studies were used. All patients had chronic liver disease. Agreements were evaluated with kappa index (κ) and intraclas correlation coefficient (Ric). Results. 1/ Intra method agreement. Blood tests. In study 1, 33 patients and 12 laboratories were included; Ric was: APRI: 0.897, FibroMeter: 0.942. In study 2, 20 patients and 10 laboratories were included; Ric was: APRI: 0.949, Fibrotest: 0.984, FibroMeter: 0.963. In study 3, 33 patients and 2 laboratories were included; Ric for FibroMeters was: virus: 0.991, alcohol: 0.976, NAFLD: 0.990. Liver biopsy. Intra center agreement. In study 4, the Metavir staging was evaluated in 44 patients by 4 pathologists from an academic hospital: κ=0.59. In study 5, agreement was evaluated between one senior and one junior expert in 157 patients: κ=0.48. Inter center agreement. In 1998 (study 6), agreement was evaluated in 26 patients between an academic senior expert and 10 non-expert out-pathologists: κ=0.13 and Ric=0.69. In 2003 (study 7), 33 patients were evaluated by 8 out-pathologists: κ=0.18 and Ric=0.69. In 2004, the agreement was between one expert from the Metavir group and 6 out-pathologists in 205 chronic hepatitis C (study 8): κ=0.336 and Ric=0.649. Fibroscan. 46 patients and 4 observers were enrolled into the study 9: Ric=0.93. 2/ Comparison between methods. Non invasive tests translated into Metavir F stages. The agreement of FibroMeters was: Ric=0.965, κ=0.874 (study 3). Agreement of Fibroscan was: Ric=0.84-0.89, κ=0.63-0.65 (study 9). Misclassification rates. The misclassification rates for significant fibrosis were: blood tests: FibroMeter: 23.3%, Fibrotest: 27.9%, Hepascore: 27.8% in 825 patients (study 10); liver biopsy: 22.9% against senior expert (study 8), 9.6% against consensus reading (study 5); Fibroscan: 16.5% in 194 patients (study 11), 20% in 65 patients (study 11) and 24.1% in 461 patients (study 13). Conclusions. Intra method reproducibility is as follows: blood test > Fibroscan > histology. Considering the liver interpretation by a senior expert or consensus reading as the reference, the agreement between measurements is as follows: blood test > Fibroscan > histology. In routine practice, the observed misclassification rate of non invasive tests is similar to that of liver biopsy. Finally, liver biopsy should be considered as a specialized tool read by experts whereas non invasive tests are more reproducible in clinical practice.

HISTOLOGICAL OUTCOMES AFTER 30 YEARS IN UNTREATED IRISH WOMEN WITH CHRONIC HCV GENOTYPE 1B, DO GENETIC FACTORS INFLUENCE?
Sharon Barrett1, John A. Browne1, Conor O’ Keane1, Robert A. Levine2, 1Centre for Liver Disease, Mater University Hospital, Dublin 7, Ireland; 2Department of Medicine, State University of New York, Upstate Medical University, Syracuse, New York, NY

Background and Aims: The cohort of Irish women infected with Hepatitis C virus (HCV) genotype 1b in 1977, represent a unique homogenous group to investigate the natural course of HCV infection. We have previously demonstrated strong genetic associations with viral clearance in this cohort. More recently, we have demonstrated minimally progressive disease and histological improvement (after 27 years) in serial liver biopsies. To date we have not investigated whether genetic factors are responsible for the favourable histological outcomes observed in serial liver biopsies. In the current study we aim to describe the natural history of infection after 30 years and to investigate whether genetic factors including HLA Class I and Class II (DRB1 and DQB1) alleles or polymorphisms of TNF-alpha, TGF-beta, IL-10, IL-6, and IFN-gamma genes could predict biochemical or histological outcomes. Methods: The study cohort comprised of 56 untreated women with persistent viremia who had paired or multiple liver biopsies. All were infected with HCV genotype 1b in 1977. Biochemical (alanine aminotransferase [ALT]) and histological assessments in serial liver biopsies were performed. Baseline and sequential biopsy specimens were assessed for grade (increase/decrease of 2 points) and stage change (increase/decrease of 1 point). Genotyping for the various genetic markers was carried out on genomic DNA using polymerase chain reaction sequence-specific primers. Results: The mean age of the 56 women at the time of baseline biopsy was 44.3 [range 23-57]. The mean baseline grade and stage scores were 3.89 [range 2-9] and 0.72 [range 0-3] respectively. Mean number of biopsies was 2.73±0.7 and mean interval to last biopsy was 7.5 years [range 1-13]. Over this time period, grade scores remained unchanged in 51.8%, increased in 28.6% and improved in 19.6% patients; stage scores remained unchanged in 55.4%, increased in 17.9% and improved in 17.9% patients. The mean baseline ALT was 45.5 [range 11-110]. There were positive correlations between baseline ALT, grade and stage and between sequential grade and stage scores. Only DQB1 0203 was associated with increased ALT values (p<0.024). There were no significant associations between genetic factors and histological outcomes. Conclusion: A benign course of HCV genotype 1b infection with 17.9% disease regression was observed in untreated women with paired or multiple liver biopsies 30 years after infection. Genetic factors including HLA Class I and Class II (DRB1 and DQB1) alleles or polymorphisms of TNF-alpha, TGF-beta, IL-10, IL-6, and IFN-gamma genes do not account for this favourable histological outcome.

HIGHER CAFFEINE CONSUMPTION IS ASSOCIATED WITH Milder FIBROSIS IN PATIENTS WITH CHRONIC LIVER DISEASES

Apurva A. Modi1, Jordan J. Feld1, Yoon Park1, James Everhart2, T. Jake Liang1, Jay H. Hoonfagle1; 1Liver Diseases Branch, NIDDK, NIH, Bethesda, MD; 2Epidemiology and Clinical Trials Branch, NIDDK, NIH, Bethesda, MD

Introduction: Two recent population-based surveys (NHANES I and III) have reported that higher caffeine consumption was associated with lower risk of elevated ALT levels and lower risk of chronic liver disease (CLD). Aim: To develop an instrument to assess caffeine consumption and evaluate the association of caffeine intake with severity of fibrosis in pts with CLD. Methods: A questionnaire aimed at measuring caffeine consumption over the previous month was developed and administered to all pts undergoing liver biopsy. Modified from a Nurses Health study questionnaire, it asked the frequency of consumption of caffeine-containing foods and beverages, including soft drinks, coffee, tea, cocoa as well as caffeine-fortified drinks, chocolate bars, caffeine-containing medications and alcohol intake. Caffeine consumption was quantified as the average mg of caffeine per day in which one 8 oz cup of coffee = 136 mg. Routine liver tests were obtained at the time of questionnaire completion, and liver histology was scored using a modified Ishak scoring system for activity and fibrosis. Logistic regression was performed to evaluate the association of caffeine with advanced liver fibrosis (Ishak score≥3).

Results: Among the 182 pts (60% male, 58% Caucasian, mean age 48 years), 112 had HCV, 38 HBV, 3 HDV, 21 NASH, 4 PBC and 4 AIH. 137 pts underwent liver biopsy and 30% had advanced fibrosis. The average caffeine intake was 193 mg/day (~1.5 cups of coffee/day). No patient reported more than minimal alcohol intake. Repeat administration of the questionnaire (> 2 weeks after initial) demonstrated consistency in reporting of caffeine intake (Cronbach coefficient alpha = 0.97). Among the entire cohort, after adjusting for other factors known to be associated with fibrosis (age, sex and baseline ALT), caffeine intake ≥ 300 mg/day (~2.2 cups of coffee daily) was associated with reduced fibrosis compared to lesser amounts or no caffeine intake (OR=0.39, 95% CI 0.15-1.03, p=0.057). The effect of caffeine was even more pronounced in pts with HCV. HCV pts with caffeine intake ≥ 300 mg/d were 88% less likely to have advanced fibrosis than pts with lower consumption both by univariate and multivariate regression (adjusted OR=0.22, 95% CI 0.06-0.89, p= 0.03). Higher caffeine consumption was also independently associated with ALT values below the median (58 IU/l) for the HCV cohort (OR=0.37 95% CI 0.15-0.92, p=0.03). Conclusions: Higher caffeine consumption is associated with milder fibrosis in pts with CLD, particularly those with HCV infection.

LARGE SCALE VALIDATION OF THE SAFE (SEQUENTIAL ALGORITHMS FOR FIBROSIS EVALUATION) BIOPSY IN CHRONIC HEPATITIS C

Giada Sebastiani1, Philippe Halfon2, Laurent Castera3, Stanislav Pol4, David L. Thomas5, Alessandra Mangia6, Vito Di Marco7, Mario Pipiri8, Mihai Voiculescu9, Marc Bourliere10; 1VIMM-Venetian Institute of Molecular Medicine, Padova, Italy; 2Laboratoire Alphabio, Hospital Ambroise Pare, Marseille, France; 3Service d’Hépatogastroentérologie, Hôpital Haut Lévêque, C. H. U. Bordeaux, Passac, France; 4Liver Unit and Inserm U-567, Cochin Hospital, Paris, France; 5Johns Hopkins School of Medicine, Baltimore, MD; 6Division of Gastroenterology, Hospital Casa Sollievo della Sofferenza, IRCCS, San Giovanni Rotondo, Italy; 7Cattedra e Unità Operativa Complessa di Gastroenterologia ed Epatologia, University of Palermo, Palermo, Italy; 8Dipartimento di Medicina Clinica e Sperimentale, Università del Piemonte Orientale, Novara, Italy; 9Department of Internal Medicine and Nephrology, Fundeni Clinical Institute, Bucharest, Romania; 10Hôpital Saint Joseph, Marseille, France

Background: Noninvasive methods have been proposed in hepatitis C as surrogates of liver fibrosis but their diagnostic performance is not such to completely substitute liver biopsy. Moreover, large validation studies are still pending. We have recently proposed sequential algorithms that combine AST/Platelets Ratio Index (APRI) and Fibrotest (FT) with liver biopsy, with excellent performance and >50% reduction in liver biopsy needed (J Hepatol 2006;44:686-93). These algorithms (SAFE biopsy) are based on sequential use of APRI and FT, restricting liver biopsy to cases in which these noninvasive markers show insufficient accuracy. Aim: large-scale validation of the SAFE biopsy to identify significant fibrosis (≥F2) by METAVIR and cirrhosis (F4) in hepatitis C. Methods: International, multicenter study of 1978 HCV monoinfected cases (1112 males, 866 females; mean age: 46.9±11.9yrs). FT and APRI were measured at the time of liver biopsy, taken as gold standard. Subgroup analysis was conducted to determine whether age, gender, HCV genotype and BMI modify the performance of SAFE biopsy. Results: Performance of the SAFE biopsy using the cutoff for APRI and FT of the original studies is shown in table. Overall, SAFE biopsy for significant fibrosis saved 47.1% of liver biopsies with >95% accuracy. SAFE biopsy for cirrhosis also had excellent performance and saved 82% of liver biopsies. The performance of SAFE biopsy was excellent across all major HCV genotypes while it was somehow reduced for ≥F2 with age >50yrs (AUC=0.83, p=0.001 vs. overall AUC) and for F4 with BMI>30 (AUC=0.84, p=0.01). Therefore, specific cutoff for FT (0.57 for ≥F2; 0.84 for F4 with BMI>30) were identified, allowing to optimise the performance of SAFE biopsy (AUC=0.87 for ≥F2 with >50yrs; AUC=0.90 for F4 with BMI>30). SAFE biopsy applied to HCV patients with normal ALT showed excellent performance (AUC=0.94 for ≥F2; AUC=0.89 for F4). Conclusions: this large-scale, multicenter validation study confirms that SAFE biopsy is a rational way of combining noninvasive markers with marked reduction in liver biopsies needed to correctly classify liver fibrosis in hepatitis C. This approach can be useful for large scale screening of HCV patients.

1343 ANTI-LIVER KIDNEY MICROSMO TYPE ONE (αLKM1) POSITIVE HCV-RELATED CHRONIC LIVER DISEASE: PRESENTATION AND FOLLOW UP

Silvia Ferri, Giorgio Ballardini, Valentina Cipriano, Alessandro Granito, Alberto Grassi, Luigi Muratori, Paolo Muratori, Georgios Pappas, Chiara Quarneti, Francesco B. Bianchi, Marco Lenzi; Department of Internal Medicine, Cardioangiology and Hepatology, University of Bologna, Bologna, Italy

Our study aims to explore presentation and follow up of anti-LKM1 positive HCV-related chronic liver disease (CLD). Methods: 63 patients with anti-LKM1 positive HCV-related CLD (LKM) were matched for age (median 51 years) and sex (M/F = 78/111) with 126 controls with HCV related CLD negative for non-organ specific autoantibodies (NOSA) (C); no differences in viral genotype distribution were observed between LKM and C. The evaluation was made at the time of presentation in our liver unit and after a median follow up of 72 (LKM) and 51 (C) months. NOSA presence was tested by indirect immunofluorescence (IFL) at a 1:40 serum dilution. On frozen hepatic liver sections, HCV-antigens and CD8 lymphocytes were evaluated by an immunoperoxidase technique and their number estimated. Conclusions: Our data indicate a more active disease in LKM patients (higher transaminase levels, more frequent advanced disease at presentation). Higher immunoglobulin and hepatic CD8 cell levels, in association with lower HCV-infected hepatocytes, suggest that at least in part the hepatic damage in LKM could be autoimmune-driven via molecular mimicry mechanisms between HCV polyprotein and CYP450IID6. This hypothesis is supported by the frequent disappearance of anti-LKM1 antibody after antiviral therapy in long term responders (84.6%) compared to 44.4% in non responders/relapsers (p < 0.0743). Although anti-LKM presence doesn’t seem to affect antiviral therapy results, hepatic flares occurring in LKM suggest the importance of a careful monitoring of these patients under treatment.

ently associated with the median inter-observer gap (P < 0.001). Four groups (Gr) were defined according to IQR/LSM. Gr1: Both operators found an IQR/LSM < 0.2 (n = 119): median inter-observer gap = 0.15; ICC = 0.69 and kappa index = 0.87; Gr2: At least one of the two operators found an IQR/LSM > 0.2 and < 0.3 (n = 124): median inter-observer gap = 0.21; ICC = 0.68 and kappa index = 0.86; Gr3: At least one of the two operators found an IQR/LSM > 0.3 and < 0.5 (n = 84): median inter-observer gap = 0.23; ICC = 0.64 and kappa index = 0.80; Gr4: At least one of the two operators found an IQR/LSM > 0.5 (n = 42): median inter-observer gap = 0.41; ICC = 0.41 and kappa index = 0.58. The ICC and kappa index of Gr1 were different from those of the 3 other groups (P < 0.05). Conclusion: The reproducibility of transient elastography is excellent. However, IQR/LSM is a key factor of inter-observer agreement. The reproducibility of transient elastography is significantly reduced in patients with IQR/LSM > 0.2. 1) Ganne-Carrié et al. Hepatology 2006;44:1511-7.

1345 THE USE OF NEW NORMAL ALT VALUES DIFFERENTIATE BETTER PATIENTS WITH HBeAg NEGATIVE CHRONIC HEPATITIS B FROM INACTIVE CHRONIC CARRIERS

Nimer Assy1,2, Zaza Beniashvili1, Maria Grosovski2, Smadar Dabush1, Patia Erdstein1, Bayan Hino1,2; 1Liver Unit, Sieff Hospital, Safed, Israel; 2Biotechnology, Ort Braude, Karmiel, Israel; 3Faculty of Medicine, Technion, Haifa, Israel

Background: Wild type HBeAg-positive CHB, inactive healthy carriers and HBeAg negative CHB are the three most common clinical forms of chronic hepatitis B infection (CHB). Aim: To determine whether the new normal ALT values and lower HBV DNA cut-off levels differentiate better patients with HBeAg negative CHB from inactive chronic carriers. Methods: Of 240 chronic HBV infected patients, 90 patients were tested for HBV DNA levels by PCR-based assay [Cobas Amplicor HBV Monitor, Sensitivity <200 copies/ml]. HBeAg-positive patients with normal ALT (immune tolerant) and patients with co-infection with HCV or HIV were excluded. ALT levels were tested twice during the last six months [new normal values: ULN 30 IU for male, 19 IU for female]. Results: 31 patients were HBeAg-positive, 19 inactive HBsAg carriers (HBeAg negative, ALT normal) and 40 HBeAg-negative CHB [ALT elevation]. There was no significant difference in inflammatory grade (4.6±1.9 Vs 4.4±1.2, P<0.5) and in fibrosis stage (1.3 ±1.4 Vs 1.1±1.3) between HBeAg-positive and HBeAg-negative patients respectively. Serum HBV DNA levels of the HBeAg-negative patients were significantly lower than those of the HBeAg-positive patients (Median 2.0×10E+5 Vs 1.9×10E+11 copies/ml, P < 0.0001) and higher than those of the inactive healthy carriers (Median 2.0×10E+5 Vs 4.1×10E+10 copies/ml, P<0.001). Using the normal new ALT definition, the lowest optimal HBV DNA levels that differentiate between HBeAg-negative CHB from inactive carriers was 50.000 cc/ml (91% accuracy, NPV 95%, PPV 78%, SS 78%, SP 93%) and not the recent suggested HBV DNA cut-off of 5000 cc/ml (70% accuracy, NPV 52%, PPV 76%, SS 75%, SP 57%). The diagnostic accuracy of HBV DNA levels was similar with the 50,000 and 100,000 cut-off level. The serum HBV DNA levels were lower than the cut-off value in 97% (18/19) of the inactive carriers, and in 27% (11/40) of the HBeAg negative CHB patients. If ALT values are less than <30 in men and less than <19 in women and HBV DNA levels <100,000, the risk of having HBeAg-negative CHB is 4%. On the other hand, if ALT values are more than >30 in men and more than >19 in women and HBV DNA levels is more than >100,000, the risk of HBeAg−negative CHB is 80%. Conclusion: using the new normal ALT values, HBV DNA level <100,000 proposed by NIH workshop to characterize inactive carriers is appropriate.

1346 THE RESULT OF LIVER STIFFNESS MEASUREMENT IS INFLUENCED BY THE SERUM BILIRUBIN LEVEL

Yeon Seok Seo1, Sang Jun Suh1, Yong Dae Kwon1, Sanghun Park1, Bora Keum1, Beom Jin Park2, Yong Sik Kim1, Yoon Tae Jeen1, Hoon Jai Chun1, Chang Duck Kim1, Ho Sang Ryu1, Soon Ho Uhm1; 1Internal Medicine, Korea University College of Medicine, Seoul, South Korea; 2Radiology, Korea University College of Medicine, Seoul, South Korea

Background/Aim: Although liver stiffness measurement (LSM) using FibroScan is usually well correlated with the fibrosis score on liver biopsy, discrepancies between the results of LSM and fibrosis score could appear in some patients. Until now, except fibrosis score, any factors which could influence the result of LSM were not identified. This study was performed to evaluate whether acute liver injury could affect the result of LSM. Methods: All consecutive patients with acute hepatitis who admitted to our hospital during 6 months were included. Patients with previous or family history of liver disease were excluded. These patients were subjected to FibroScan during admission and followed-up 1-6 months later. At the time of LSM, serum AST, ALT, ALP, GGT and bilirubin levels were examined. For validation, correlation between the LSM and fibrosis score were compared according to the results of biochemical tests in patients who underwent liver biopsy and LSM. Results: Seventy-five patients with acute hepatitis were enrolled [median age, 30 years; M:F; 40:35]. The causes of acute hepatitis were acute hepatitis A in 61 patients, acute hepatitis B in 3, toxic hepatitis in 8, and others in 3. Baseline LSM was 10.6±6.9 kPa (median, 8.8). There was no difference in the results of AST, ALT, ALP and GGT between patients with higher LSM and lower LSM, but bilirubin level was significantly higher in patients with high LSM (P=0.024). Bilirubin level was the only significant correlated factor with LSM in bivariate correlation analysis (Kendall's correlation coefficient, 0.331; P <0.001). LSM decreased to ≤6 kPa in 44 patients during follow-up. The duration for LSM ≤6 kPa was not different according to sex, age, cause of acute hepatitis, the levels of ALT, AST, ALP, and GGT, but it was significantly longer in patients with higher bilirubin level (80±11 days) than patients with lower bilirubin level (36±4 days; P <0.001). Similarly, bilirubin level was the only significant factor on multivariate analysis (OR, 0.265; 95% CI, 0.127-0.525). In 92 patients who performed liver biopsy, Kendall's correlation coefficient between the results of LSM and fibrosis stage was 0.553 and AUROC for ≥F2, ≥F3, and F4 was 0.808, 0.877, and 0.913, respectively. When 7 patients with jaundice were excluded; the improvement of correlation and increase of AUROC were noted (Kendall's correlation coefficient, 0.650; AUROC for ≥F2, ≥F3, and F4, 0.891, 0.915, and 0.923, respectively). Conclusion: Serum bilirubin level seems to affect the result of LSM. Caution is required when interpret the result of LSM in patients with jaundice.

Obesity is a contributing factor to the development of steatosis and in treatment failure in chronic HCV. Aims: Evaluate the interaction between obesity and fibrosis progression in a cohort of HCV patients with paired liver biopsies. Methods: We identified all HCV patients with at least two liver biopsies (1997-2006). Patients with insufficient tissue (<10 portal tracts) or lack of body mass index (BMI) were excluded. A hepatopathologist scored 215 biopsies from 102 patients for necroinflammation (modified histologic activity index [HAI]) and fibrosis (Ishak, stage 0-6). A change by at least one histologic stage was used to define progression or regression. Univariable and multivariable logistic regression analysis was performed to assess the association of baseline factors with advanced fibrosis on each of the paired biopsies separately. To assess factors associated with progression between the two biopsies, a Cox regression model was used. Backward elimination method was used to select factors included in the final model. Results: Time between 1st and 2nd biopsy was 1-13.5 years in which 43% of subjects had progression, 29% had no change and 27% had regression. Rate of change between 1st and 2nd biopsy was -0.16 to 0.49 units annually. Older age, higher HAI score and diabetes were independently associated with advanced fibrosis in 1st and 2nd biopsy. Obesity (BMI >30) was the only factor found to be significantly associated with fibrosis progression between 1st and 2nd biopsy by univariable (P=0.023) and multivariable (P=0.006) analysis, independent of antiviral therapy. A Kaplan-Meier plot was constructed (Figure) to outline the association between obesity and fibrosis progression. Conclusions: 1)Older age, higher HAI score and diabetes in chronic HCV patients are independently associated with advanced fibrosis in a cross-sectional single time point biopsy. 2)Using paired biopsy specimens, obesity is a strong predictor of fibrosis progression over a defined time interval between biopsies.

Accurate identification of liver fibrosis using the point-of-care continuous 13C methacetin breath test: a decision making tool in the treatment of patients with chronic HCV infection

Gadi Lalazar1, Orit Pappo 2, Yaron Ilan 1; 1Liver Unit, Hadassah Hebrew University Medical Center, Jerusalem, Israel; 2Department of Pathology, Hadassah Hebrew University Medical Center, Jerusalem, Israel

Current treatment of chronic HCV infection is based on the degree of hepatic fibrosis. Liver biopsy has been the gold standard for this assessment. The point-of-care non-invasive BreathID® continuous online 13C methacetin breath test (MBT) reflects hepatic microsomal function (CYP1A2) and was shown to correlate accurately with the degree of hepatic fibrosis. Aim: To develop a treatment algorithm for patients with chronic HCV infection based on detection of the degree of liver fibrosis using MBT. Methods: 100 patients with chronic HCV infection and 100 healthy, age and sex-matched controls underwent 13C MBT following ingestion of 75 mg methacetin. All HCV patients had undergone a liver biopsy within 6 months of performing the MBT. Breath test parameters tested included PDR Peak (percentage dose recovered), PDR Peak Time, and both PDR and CPDR (cumulative PDR) 10, 20, 30 and 60 minutes after ingestion of methacetin, respectively. The correlation between breath test parameters and the Ishak modified histological activity index (HAI) fibrosis score, age, weight and BMI was determined. The ability of MBT to correctly identify liver fibrosis was assessed. Patients with a HAI fibrosis score ≤ 2 or > 2 were defined as non-significant or significant fibrosis, respectively. Results: MBT parameters were significantly correlated with the stage of fibrosis (p<0.0001). By using an algorithm that includes age, PDR Peak, PDR Peak Time, PDR30 and CPDR20-60, 67% of liver biopsies performed in the patient group could have been avoided. This algorithm achieved an area under the curve (AUC) of 0.92, with a sensitivity of 91% and a specificity of 88%, a PPV of 88% and NPV of 91%. Thirty three patients were identified as having significant fibrosis, including 4 false positives; two with a HAI fibrosis score of 2 and an additional two with a score of 1. Thirty four patients were identified as having non-significant fibrosis including 4 false negatives; two with a HAI fibrosis score of 3 and one with a score of 5. There was no correlation between age or BMI and MBT scores for patients with the same histological score. Conclusions: The BreathID® continuous online 13C MBT accurately detects liver fibrosis in patients with chronic HCV infection enabling a non-invasive alternative to liver biopsy. Using the above algorithm, liver biopsy could have been avoided in two thirds of this patient population. MBT is a practical non-invasive tool for decision-making in the evaluation of patients with chronic HCV infection.

Iron overload does not affect the quantification of fibrosis by liver stiffness measurement

Vito Di Marco¹, Fabrizio Bronte¹, Daniela Cabibi², Francesco Barbària¹, Zelia Borsettino³, Giuseppe Alaimo¹, Vincenza Calvaruso¹, Stefania Ciminnisi³, Marcello Capra³, Aurelio Maggio⁴, Piero Luigi Almasio¹, Antonio Craxi²; ¹Dipartimento di Medicina Interna e Specialistica, University of Palermo, Palermo, Italy; ²Servizio di Istitologia, University of Palermo, Palermo, Italy; ³Servizio Telassemia, Ospedale Pediatrico “G. Di Cristina”, Palermo, Italy; ⁴Servizio Telassemia, Ospedale “V. Cervello”, Palermo, Italy.

Background and aims: Several studies report a close relation between liver stiffness measured by FibroScan (Echosens, France) and fibrosis evaluated by liver biopsy (LB), but the influence of iron overload on liver stiffness measurement (LSM) is unknown. Aim of our study was to evaluate the correlation between liver fibrosis, iron overload and LSM in patients with Homozygous β-Thalassemia (HbT) and in patients with chronic hepatitis C. Methods: 52 patients with HbT (mean age 27 years; 18 HCV RNA positive and 34 HCV RNA negative) and 104 non-thalassemic adults with chronic hepatitis C (mean age 55±10.6 years, mean BMI 27.3±4.7 Kg/m2) underwent LB (mean length of biopsy 17 mm) and simultaneous LSM. Liver inflammation and fibrosis were scored according to METAVIR, steatosis according to Brunt’s score and LIC was measured on fresh tissue cores by atomic absorption spectrometry and was expressed as mg/gr of liver dry weight (normal values < 1.6 mg/gr). Results: The degree of liver fibrosis, the LSM expressed as KPa, and the LIC in patients with HbT and in patients with chronic hepatitis C are reported in the table 1. LSM increased proportionally to the METAVIR stage, with a highly significant relation to fibrosis (rho= 0.70; p <0.001 by Spearman’s test) independently of LIC values (r= 0.16; p= 0.07 by Spearman’s test), both for thalassemics and non-thalassemics patients. At univariate analysis, LSM correlated with histological grading (95% CI: 3.0–37.5; p < 0.0001), presence of steatosis (p < 0.0001) and degree of fibrosis (95% CI: 2.8–37.5; p < 0.0001). At multivariate analysis, presence of steatosis (r= 0.362; p < 0.0007 and fibrosis (r= 0.684; p < 0.0001) remained factors associated with LSM. LSM had excellent value proportionally to the METAVIR stage, with a highly significant relation to fibrosis (rho= 0.70; p <0.001 by Spearman’s test) independently of LIC values (r= 0.16; p= 0.07 by Spearman’s test), both for thalassemics and non-thalassemics patients. At univariate analysis, LSM correlated with histological grading (95% CI: 3.0–37.5; p < 0.0001), presence of steatosis (p < 0.0001) and degree of fibrosis (95% CI: 2.8–37.5; p < 0.0001). At multivariate analysis, presence of steatosis (r= 0.362; p < 0.0007 and fibrosis (r= 0.684; p < 0.0001) remained factors associated with LSM. LSM had excellent value in discriminating patients with F4 fibrosis (i.e. cirrhosis), but was less performing at lower stages of fibrosis. Conclusion: LSM by FibroScan is an adequate and reliable non-invasive tool to diagnose advanced liver fibrosis even in subjects with severe liver iron overload.

Liver fibrosis, LSM (expressed as KPa) and the LIC (expressed as mg/gr of liver dry weight) in patients with HbT and in patients with chronic hepatitis C

HCV genotype determination in clinical practice: weaknesses of assays based on the 5'-noncoding region and improvement with the core-coding region

Stephane Chevaliez, Magali Bouvier-Alias, Claire Vandervenet, Jean-Michel Pawlotsky; Henri Mondor Hospital, University of Paris 12, Creteil, France.

HCV genotype determination is mandatory to tailor peginterferon-ribavirin treatment dose and duration. Subtype determination is likely to become useful to tailor specific HCV inhibitor therapy and interpret resistance data in the future. In clinical practice, genotype determination is most often based on assays targeting the 5’-noncoding region (5’NCR). However, this region does not discriminate well between the different subtypes of genotype 1 and between genotypes 1 and 6. Objectives: (i) To determine the frequency of erroneous HCV genotype 1 subtype determination with genotyping technologies targeting the 5’NCR. (ii) To assess whether targeting the core-coding region in addition to the 5’NCR improves HCV typing. METHODS: 505 clinical specimens from patients with chronic hepatitis C included in a multicenter national trial, locally considered as genotype 1, have been studied. HCV genotype-subtype determination has been performed by means of three different techniques: (i) the reference method, i.e. direct sequence analysis of a portion of the N558 coding region followed by phylogenetic analysis; (ii) direct sequence analysis of the 5’NCR (Trugene HCV 5’NCR Assay, Siemens); (iii) reverse hybrization with the second-generation line probe assay (INNO-LiPA 2.0, Innogenetics), that includes probes located in the core-coding region in addition to the 5’NCR probes. RESULTS: Among the 505 clinical specimens, the reference method showed that 496 patients were infected with HCV genotype 1, including 233 with subtype 1a, 253 with subtype 1b and 10 with another subtype, and 9 patients were infected with an HCV genotype other than 1. Among the 496 patients infected with HCV genotype 1, sequence analysis of the 5’NCR gave an erroneous subtype in 71 patients (14.3%), including 46 with subtype 1a, 15 with subtype 1b and 10 with other subtypes. In the second-generation line probe assay, the subtype was erroneous in only 19 patients (3.8%), including 4 with subtype 1a, 5 with subtype 1b and 10 with other subtypes. Among the patients infected with an HCV genotype other than 1, 6 were infected with HCV genotype 6 and all of them were correctly classified by the second-generation line probe assay. CONCLUSION: HCV genotyping assays targeting the 5’NCR misclassify HCV genotype 1 subtypes in nearly 15% of cases. Using the second-generation line probe assay, that contains probes targeting both the 5’NCR and the core-coding region, improves the accuracy of HCV genotype 1 subtyping and differentiates among genotypes 1 and 6. However, approximately 4% of the samples remain mistyped with this technique.

SERUM LEVELS OF SH2A, A SECRETED FORM OF THE ASIALOGLYCOPROTEIN RECEPTOR, AS A NON-INVASIVE SENSITIVE MARKER FOR LIVER FUNCTION
Elena Veselkin1, Maria Kondratyev1, Efrat Ron1, Moshe Santo2, Shimon Reif2, Irma Elashvili2, Lana Bar2, Yoav Lurie2, Ran Oren2, Gerardo Z. Lederkremer1; 1Cell Research and Immunology, Tel Aviv University, Tel Aviv, Israel; 2Liver Unit, Dept. of Gastroenterology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel
Study’s purpose: We have evaluated the possible use of a soluble secreted form of the human asialoglycoprotein receptor (ASGPR sh2a) as a new non-invasive marker for the sensitive assessment of liver function. The current markers (prothrombin time, albumin and others) can only detect liver dysfunction in advanced disease. On the other hand, blood levels of enzymes such as alanine and aspartate aminotransferases (ALT and AST) indicate liver damage and not function and can appear normal in many cases of liver disease or abnormal in a wide range of non-hepatic diseases. sh2a is liver-specific as it is secreted to the serum exclusively by hepatocytes. Methods: We have measured sh2a levels in serum using a monoclonal antibody and an ELISA assay that we developed, comparing with routine liver function tests. Results: We determined in a series of double blind studies that sh2a was present at very constant levels in serum from 57 out of 63 healthy control individuals. The <10% of controls that showed abnormal levels of sh2a also revealed borderline levels for one or more of the established liver function markers. A study of 43 HCV patients showed abnormal sh2a values in 25% of those at fibrosis stage 0, 37% of those at stage 1, 57% at stages 2-3 and 100% at stage 4 (cirrhosis). The combined analysis of sh2a levels and those of ALT and AST allows prediction of fibrosis stage. Conclusions: sh2a appears to be a uniquely sensitive marker of liver function with potential widespread use. In combination with routine markers it could also be used for non-invasive determination of fibrosis stage.

COMPARISON OF A NEW ASSAY FOR HEPATITIS C VIRUS (HCV) GENOTYPING TARGETING BOTH 5’NC AND NS5B GENOMIC REGIONS, WITH REVERSE HYBRIDIZATION AND SEQUENCING METHODS
Elisa Martro1, Victoria Gonzalez1, Andrew Buckton2, Veronica Saludes1, Ramon Planas3, Vicenç Ausina1; 1Microbiology Service, Hospital Universitari Germans Trias i Pujol, Badalona, Spain; 2Centre for Infections, Health Protection Agency, Colindale, United Kingdom; 3Digestology Department, Hospital Universitari Germans Trias i Pujol, Badalona, Spain
Responsiveness to current combined therapy varies depending on genotype. Most genotyping methods used in clinical settings target the conserved 5’NC region, while sequencing and phylogenetic analysis of more variable genomic regions, such as NS5b, is considered the reference method. Our aim was to evaluate a new assay based on real-time PCR targeting the NS5b region for genotype 1 and the 5’NC for genotypes 2 to 6 (Abbott Diagnostic) in comparison with 5’NC reverse hybridization (InnoLiPA HCV II, Innogenetics) and 5’NC sequencing (Trugene HCV 5’NC, Bayer Healthcare). After RNA extraction from serum, a total of 295 specimens were tested by real-time PCR (method 1); 223 of them were also typed by 5’NC sequencing (method 2) and 89 by hybridization (method 3) using 5’NC amplicons from Cobas Amplicor (Roche).
Sequencing and phylogenetic analysis of an NS5b fragment was used to resolve discrepant results. Suspected multiple genotype infections were confirmed by a method based on PCR-cloning and pyrosequencing of a 5’NC region. A genotype call was obtained by method 1 on 289 (97.97%) specimens, while one genotype 1, three genotypes 2, and two genotypes 3 were indeterminate. Concordance at the genotype level was high among methods 1 and 2 (214/220; Cramer’s V=0.849, p<0.005) and 1 and 3 (85/86; k=0.982, p<0.05), while concordance between methods 2 and 3 was total (17/17, k=1). Among 8 discordant results, five mixed-genotype infections were confirmed by cloning and pyrosequencing or Quality Control for Molecular Diagnostics (QCMD). Since method 1 can only detect 1a, 1b, 2a and 2b subtypes, concordance at the subtype level was not assessed for genotypes 3 to 5. Regarding genotype 1 subtyping efficiencies were 100%, 77.27%, and 73.91% for methods 1, 2, and 3, respectively. However, there were 11/101 discordants between methods 1 and 2. According to NS5b sequencing, method 1 was predominantly correct. Only 2/34 discordants were seen between methods 2 and 3. Regarding genotype 2, subtyping efficiencies were 100%, 45% and 92% by methods 1, 2 and 3, respectively. Analysis of discordant results (16/17) by NS5b sequencing revealed a putative new subtype within genotype 2, and that most subtype calls were not correct. Although only sequencing-based methods provide the possibility of identifying new variants, the real-time PCR method is quick, easy, and simple to interpret, thus providing a good single-step alternative to more time-consuming assays. While correlation with the other methods at the genotype level was high, being based on the NS5b for genotype 1 identification, the real-time PCR method performed better than the other two at assigning 1a and 1b subtypes.

1353
NATURAL HISTORY OF HEPATITIS C VIRUS INFECTION IN HIV-INFECTED INDIVIDUALS IN THE ERA OF HAART: SYSTEMATIC REVIEW AND META-ANALYSIS
Hla Hla Thein1,2, Qilong Yi3, Gregory J. Dore4, Murray D. Krahn2,5; 1Division of Clinical Decision-Making and Health Care, University Health Network, Toronto, ON, Canada; 2Toronto Health Economics and Technology Assessment Collaboration, University of Toronto, Toronto, ON, Canada; 3National Epidemiology and Surveillance, Canadian Blood Service, Ottawa, ON, Canada; 4Viral Hepatitis Program, National Centre in HIV Epidemiology and Clinical Research, University of New South Wales, Sydney, NSW, Australia; 5Departments of Medicine and Health Policy, Management and Evaluation and Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada
Our objectives were to estimate stage-specific hepatic fibrosis progression rates in HIV/hepatitis C virus (HCV) coinfected individuals and to determine factors associated with fibrosis progression in this population, including the impact of HIV on HCV disease progression. A systematic review of published prognostic studies was undertaken. Study inclusion criteria were: i) HIV and HCV infections determined by serological assays; ii) information about age at assessment of liver disease or HCV acquisition; iii) duration of HCV infection; and iv) histological fibrosis staging (F0-F4) and/or clinical diagnosis of cirrhosis. Annual stage-specific transition probabilities (F0→F1, F3→F4) were derived using the Markov maximum likelihood estimation method and a meta-analysis was performed using both fixed
and random effects models. The impact of covariates – study design (cross-sectional/retrospective, prospective, retrospective-prospective), study setting (clinical/community-based), age at/duration and mode of HCV infection, gender, alcohol consumption, HCV genotype and RNA, CD4 cell count, and highly active antiretroviral therapy (HAART) on fibrosis progression was evaluated using meta-regression models. Pre-HAART and HAART era cirrhosis rates were compared in studies reporting both HCV groups. Sixteen of 65 studies reviewed fulfilled the inclusion criteria. Mean (95% CI) fixed effects annual transition rates of the HIV/HCV coinfected individuals (82% injection drug users) were: F0→F1 0.119 (0.114, 0.125); F1→F2 0.118 (0.112, 0.125); F2→F3 0.156 (0.145, 0.169); and F3→F4 0.122 (0.109, 0.137). Random effects estimates showed comparable results. The mean (95% CI) probability of cirrhosis after 20 and 40 years was 25% (22%, 27%) and 77% (74%, 79%), respectively. All covariates of interest were significantly associated with fibrosis progression from F0→F1, while study setting and HCV RNA positivity were associated with progression from F3→F4. Overall, the rate ratio (95% CI) of cirrhosis between HIV/HCV coinfected and HCV monoinfected individuals was 2.1 (1.8, 2.5): 1.7 (1.1, 2.7) in the pre-HAART era (n=6); and 2.2 (1.9, 2.6) in the HAART era (n=10). In conclusion, our predicted estimates for cirrhosis in HIV/HCV coinfected individuals appear to be higher than published estimates for HCV monoinfection. This study improves on previous studies by using a method that does not require the assumption of constant transition rates between stages and taking into account the effects of study design and setting, clinical factors, and HAART on disease progression.

1354 VALIDATION OF SIMPLE INDEXES (FIB-4, APRI, FORNS INDEX) AND PLATELET COUNT FOR NON INVASIVE PREDICTION OF LIVER FIBROSIS IN HIV-HCV COINFECTED FRENCH PATIENTS

Laurent Castera1,2, Marc Arthur Loko1, François Dabis3, Brigitte Le Bail4, Maria Winnock5, Gaelle Coureau3, Didier Neau5; 1Hepato-gastroenterology, Hopital Haut Leveque, CHU Bordeaux, Pessac, France; 2Hepato-gastroenterology, Hopital St Andre, CHU Bordeaux, Bordeaux, France; 3INSERM U593, ISPED, Université Victor Segalen,, Bordeaux, France; 4Pathology, Hospital Pellegrin, CHU Bordeaux, Bordeaux, France; 5Infectious Diseases, Hospital Pellegrin, CHU Bordeaux, Bordeaux, France

Background: Several non-invasive indexes using routinely available parameters have been proposed recently for the prediction of liver fibrosis in patients with chronic hepatitis C. However, little information regarding the validity of these indexes in human immunodeficiency virus (HIV)-HCV coinfected patients is available. Aim: to determine the diagnostic performance of FIB4, APRI, FORNS index and platelet count for the prediction of liver fibrosis in HIV/HCV coinfected patients. Methods: 200 HIV/HCV co-infected patients (male 66%, age 40±6 yrs) of the ANRS CO3 Aquitaine Cohort who underwent liver biopsy between 1999 and 2005 and had complete data to validate all the considered tests, were studied. Liver fibrosis was assessed using METAVIR scoring system and diagnostic performance by measuring areas under the ROC curve (AUROC). Results: Significant fibrosis (F2+F3+F4) was present in 157 patients (78.5%) and cirrhosis (F4) in 19.5%. Performance of the different methods using the published cut-offs are shown in the table. Conclusion: Overall, the diagnostic accuracy of these indexes was lower in HIV-HCV coinfected patients than in HCV monoinfected patients, particularly for the diagnosis of significant fibrosis. However, the use of FIB-4, APRI or platelet count may obviate the need for liver biopsy for the diagnosis of severe fibrosis-cirrhosis in up to 55% to 85 % of cases in HIV- HCV coinfected patients.
rhosis. The AUROC values for platelet count are similar to those for indirect fibrosis markers for F2 or more or F4 (Coco J Viral Hep 2007;14:360). The use of APRI is better than platelet count for non cirrhotic fibrosis, but has the same AUROC as platelet count in cirrhosis.

1356 LIVER STIFFNESS MEASUREMENT IN PATIENTS WITH CHRONIC HEPATITIS B IS NOT AS USEFUL AS THAT IN PATIENTS WITH CHRONIC HEPATITIS C FOR THE ASSESSMENT OF LIVER FIBROSIS

Yeon Seok Seo1, Eun Sun Kim1, Yong Dae Kwon1, Sanghun Park1, Bora Keum2, Beom Jin Park2, Yong Sik Kim1, Yoon Tae Jeen1, Hoon Tae Jeon1, Hoon Jai Chun2, Chang Duck Kim2, Ho Sang Ryu2, Soon Ho Um2; 1Internal Medicine, Korea University College of Medicine, Seoul, South Korea; 2Radiology, Korea University College of Medicine, Seoul, South Korea

Background/Aim: Recent studies suggested that liver stiffness measurement (LSM) using Fibroscan is noninvasive and useful for assessment of liver fibrosis. However, most studies only enrolled patients with chronic hepatitis C (CHC) and it is uncertain whether LSM would be useful in patients with chronic hepatitis B (CHB). This study was performed to evaluate the efficacy of LSM for the evaluation of liver fibrosis in patients with chronic hepatitis B and C. Methods: Patients with CHB or CHC who underwent liver biopsy were enrolled in this study. Both liver biopsy and LSM were performed in a day. Interpretation of the fibrosis score was carried out by an experienced pathologist using the Metavir scoring system (F0-F4). LSM was performed by Fibroscan. Efficacy of LSM and optimal cutoff values for fibrosis stage assessment were determined by a receiver-operating characteristics (ROC) curve analysis. Results: Ninety-one patients with CHB (n=64) or CHC (n=27) were enrolled. Median age was 40 (39±13; 14-68) years (M:F, 61:30). Fibrosis score on liver biopsy was F0-1 in 27 patients, F2 in 27, F3 in 26, and F4 in 11. Serum ALT and bilirubin level was 134.7±191.2 (median, 58) IU/L and 0.8±0.4 (median, 0.8) mg/dL, respectively. LSM was well correlated with fibrosis score (Kendall’s correlation coefficient: 0.617; p<0.001) in all patients. The areas under the ROC curve were 0.901 (95% CI, 0.839-0.963) for patients with significant fibrosis (F≥2), 0.899 (0.832-0.966) for patients with severe fibrosis (F≥3) and 0.882 (0.811-0.955) for patients with cirrhosis (F = 4). Optimal LSM cutoff values were 7.15 kPa for F≥2, 11.9 kPa for F≥3, and 13.85 kPa for F = 4. LSM was better correlated with fibrosis score in patients with CHC (0.773; p<0.001) than in patients with CHB (0.557; p<0.001). Furthermore, the areas under the ROC curve were larger in patients with CHC (0.944, 0.982, and 0.958 for F≥2, F≥3, and F4) than in patients with CHB (0.881, 0.863, and 0.850). The optimal cutoff values for F≥2 and F≥3 were similar in patients with CHC (7.05 and 11.4 kPa) and CHB (7.15 and 10.75 kPa), but sensitivity and specificity was superior in patients with CHC. Conclusions: LSM is a simple, safe and effective method for assessing liver fibrosis in patients with chronic viral hepatitis. The efficacy of LSM for the assessment of liver fibrosis was superior in patients with CHC than in patients with CHB.

1357 FIB4 USEFULNESS FOR MEASURING FIBROSIS CHANGES FOLLOWING ANTI HCV VIRAL TREATMENT

Bertrand Nalpas1,2, Héléne Fontaine1, Anais Vallet-Pichard1, Vincent Mallet1,2, Virginie Verkarre3, Stanislas Pol1,2,1Liver Unit, Hôpital Cochin, Paris, France; 2Inserm U 567, Hôpital Cochin, Paris, France; 3Service d’Anatomie-Pathologie, Hôpital Necker, Paris, France

Background: Liver biopsy still remains the key factor for evaluating the impact of anti-viral treatment on fibrosis. As FIB4 is a non invasive biological marker of fibrosis having a good discriminating power at time of initial diagnosis (i.e before any treatment), we wonder whether it could help to appreciate the pathological changes following therapy. Patients and methods: We selected from our file two hundred and twenty-nine HCV infected patients treated by combined therapy in whom a pre- and a post-treatment liver biopsy has been performed. They were 133 males and 96 females aged of 45 ± 11y. Mean time between treatment withdrawal and subsequent biopsy was 1.5 ± 1.1y and that between pre- and post-biopsy 2.6 ± 10days). FIB4 values before and after treatment were analysed according to changes in fibrosis score (Metavir) and to the response to treatment (positive or negative HCV RNA 6 months after therapy) at time of post-biopsy using variance analysis and non-parametric test for paired values. Results: As compared to pre-treatment values, mean post-treatment FIB4 values slightly decrease in sustained responders (n= 57 ; 1.4 ± 1.0 vs 1.2 ± 0.5, NS) while they significantly increased in non-responders (n= 172 ; 1.7 ± 1.7 vs 2.2 ± 2.2, p=0.004). Fibrosis score did not change in 117 (51%) patients. In this group, FIB4 values significantly increased in non responders (n= 85 ; 1.9 ± 0.3 vs 2.2 ± 0.20, p = 0.02) while it did not change in sustained responders (n= 32 ; 1.3 ± 0.3 vs 1.2 ± 0.4, NS). In 45 patients (19.6%), the fibrosis score increased of at least one unit: mean FIB4 value increased in the 41 non-responders to therapy (1.5 ± 1.0 vs 2.7 ± 2.3, p=0.001) and decreased in the 4 responders (2.2 ± 1.7 vs 1.1 ± 0.5, NS). Finally, in the 67 (29.2%) patients in whom the fibrosis score decreased of at least one unit, mean FIB4 value remained stable in non-responders (n= 46 ; 1.5 ± 1.5 vs 1.5 ± 1.4, NS) while it slightly decreased in responders to therapy (1.4 ± 0.8 vs 1.2 ± 0.5, NS). Multivariate analysis showed that the response to treatment was the single parameter significantly (p=0.007) associated to FIB4 variation after treatment. Conclusion: FIB4 variations following therapy are related to response to treatment, a model which fits well with the mathematical FIB4 formula mainly based on transaminase activities. However, individual changes in fibrosis scores related to treatment efficacy cannot be confidently evaluated using FIB4 in a given patient.
1358 EVOLUTION OF HEPATITIS C VIRUS (HCV) VIREMIA IN PROSPECTIVELY FOLLOWED INTRAVENOUS DRUG USERS (IVDUs) WITH DOCUMENTED ANTI-HCV ANTIBODY SEROCONVERSION PARTICIPATING IN A SWEDISH NEEDLE-EXCHANGE PROGRAM

Marianne Alanko1, Per Björkman2, Vilma Molnegren1, Leo Flamholc2, Anders Widell1; 1Medical Microbiology, Department of Laboratory Medicine of Lund University, Malmö, Sweden; 2Infectious Diseases, Department of Clinical Clinical Sciences of Lund University, Malmö, Sweden

Background: The dynamics of HCV viremia following acute HCV infection have mostly been studied in cases of symptomatic acute hepatitis C, which represent a minor proportion of incident HCV infections. We used sera drawn approximately every 3-6 months for surveillance of blood-borne viruses among participants in a needle-exchange program (NEP) to assess the longitudinal evolution of HCV viremia in incident HCV infection. Methods: Out of 1150 newly registered participants in a NEP in Southern Sweden, 1997-2005, 198 cases of anti-HCV antibody body seroconversion were identified during longitudinal follow-up. The last anti-HCV negative, the first anti-HCV positive, and one sample obtained one year after seroconversion, were tested for HCV RNA load using real-time PCR (Roche Taqman) at 1/10 serum dilution (detection limit 150 IU/mL). Results: HCV RNA was detected in 81 (41%) of anti-HCV negative pre-seroconversion sera. HCV viremia was detected in the 1 year sample in 145 cases (73%), indicating probable establishment of chronic infection. Eight patterns of longitudinal HCV viremia were observed (Median viral load, see Table): 1) undetectable HCV RNA in all samples (17; 8.6%) 2) undetectable HCV RNA pre-seroconversion and at one year, detectable HCV RNA in seroconversion sample (16; 8.1%) 3) undetectable HCV RNA in first two samples, detectable HCV RNA at one year (19; 9.6%) 4) undetectable HCV RNA pre-seroconversion, detectable HCV RNA in both later samples (65; 33%) 5) detectable HCV RNA pre-seroconversion, both later samples undetectable HCV RNA (7; 3.5%) 6) detectable HCV RNA in first two samples, undetectable HCV RNA one year later (13; 6.6%) 7) detectable HCV RNA pre-seroconversion and at one year, undetectable HCV RNA in first post-seroconversion sample (17, 8.6%) 8) detectable HCV RNA in all samples (44; 22%). Conclusions: Several different patterns of HCV viremia were observed in acute hepatitis C in this cohort of IVDUs, most of whom had subclinical acute HCV infection. Chronic infection developed in 73% of cases and HCV viremia was detected in 41% of the last anti-HCV negative pre-seroconversion samples.

Median viral HCV RNA load*(IU/mL) during follow-up in IVDUs with anti-HCV antibody seroconversion.

1359 FREQUENCY AND SIGNIFICANCE OF F-ACTIN ANTIBODIES (FAA) IN HIV/HCV CO-INFECTED PATIENTS

Mohamad Rasm AlSibae1,2, Ilan S. Weissberg1,2, Andrew H. Talal1,2, Ira M. Jacobson1,2; 1Center for the Study of Hepatitis C, New York, NY; 2Division of Gastroenterology and Hepatology, Weill Cornell Medical Center, New York, NY

Background: Autoantibodies are commonly observed in chronic HCV. Smooth muscle antibodies (SMA) are heterogeneous antibodies reactive to various cytoskeletal elements, such as actin, desmin, and tubulin. F-actin antibodies (FAA) are reportedly sensitive and specific for autoimmune hepatitis (AIH) and believed to be rare (<5%) in viral hepatitis. The presence of FAA predicts a subset of AIH patients with aggressive disease with increased mortality and liver failure requiring transplantation. The recent FDA approval of an ELISA detection system has made FAA testing available for routine clinical use. Hypothesis: Due to non-specific B-cell activation, HIV infection hypergammaglobulinemia and increased risk for autoimmune disorders. We hypothesized that HIV/HCV co-infected patients were more likely than HCV monoinfected controls to develop FAA and that FAA positivity would be associated with more advanced liver disease. Methods: 40 HIV/HCV co-infected patients and 51 HCV monoinfected controls were evaluated at a large academic hospital in New York City from June 2005 to June 2007. Patients randomly selected for inclusion had serologic testing for FAA and biopsy proven viral hepatitis without autoimmune features. Retrospective chart review was performed and extracted data included age, gender, HCV genotype, treatment history, serum protein-albumin gradient, ANA, and FAA. Using the Metavir scale, histologic data was evaluated for the presence of advanced inflammation (grade > 3) and fibrosis (stage > 3). Results: Co-infected patients and monoinfected controls possessed similar demographic and baseline characteristics with respect to mean age (49 vs. 51 years), genotype 1 (84% vs. 88%) and treatment status (84% vs. 88% treatment naive). Women were more prevalent in the coinfected group (65% vs. 45%). FAA were frequently observed in both co-infected (45%) and monoinfected controls (25%) (p =0.053). In HIV/HCV coinfected, the presence of FAA was associated with increased necroinflammatory grade > 3 (39% vs. 5%, OR 2.3, p = 0.02) and increased risk of advanced fibrosis stage > 3 (56% vs. 23%, OR 2.1, p = 0.03). For the HCV monoinfected patients, there was a trend towards increased disease activity with FAA positivity, however this association failed to reach statistical significance for both inflammation (31% vs. 23%, OR 0.5, OR > 0.5) and fibrosis (62% vs. 35%, OR 1.69, p > 0.05). Conclusion: FAA were observed in mono- and coinfected HCV patients at a frequency much higher than the reported literature. FAA may be markers of high grade inflammatory activity and/or fibrosis, especially in HIV/HCV coinfection.

CAUSE OF DEATH IN PATIENTS WITH HEPATITIS C (HCV)-MIXED CRYOglobulinemia (MC) Vasculitis

Samy Scerra1, Dan Landau1, David Saadoun1, Mathieu Resche-Rigon2, Aurélien Delluc, Damien Sene1, Jean Charles Piete1, Patrice Cacoub1; 1Service de Médecine Interne, Université Pierre et Marie Curie-Paris 6, CNRS, UMR 7087; AP-HP, Hôpital Pitié-Salpêtrière, Paris, France; 2Department of Biostatistics and Medical Data Processing; INSERM U717, Hôpital Saint-Louis, Paris, France

Patients and Methods: Inclusion criteria: 1) chronic HCV infection (HCV RNA+), 2) signs of MC vasculitis with the triad of purpura-arthritis-asthenia and sometimes renal or neurological involvement. The 23 patients who died between 1989 and 2006 were compared to 74 consecutive HCV MC patients followed during the same period in the same department who survived. Logistic regression analysis was used to determine independent prognostic factors. Results: Main characteristics of HCV MC patients who died were: 17 (65%) males, mean age 66 yrs, HCV infection duration 16 yrs (2-35), genotype 1 (n=17, 74%). Metavir score Activity=1.3 (0-3), Fibrosis=2.3 (0-4). Associated conditions: cardiovascular (7), alcoholism (4), autoimmune disease (2), chronic lung disease (2), depression (1). MC vasculitis signs at presentation were: peripheral neuropathy (n=19, 83%), purpura/skin ulcers (13, 57%), arthralgia (11, 48%), glomerulonephritis (9, 39%), central nervous system (3, 13%), digestive tract (2, 9%), poor general condition (11, 48%). MC was type II (n=18, 78%), creatininemia 162 micromol/l (58-630) with 9 patients having a renal insufficiency. After HCV treatment [IFN, PegIFN, Ribavirin], the virological response was: non-response (n=16), sustained (n=2), response-relapse (n=2). Other treatments included: steroids (n=15, 65%), plasmapheresis (n=11, 48%), immunosuppressors (n=9, 39%). After treatment, 17/23 patients had a clinical response of vasculitis features [complete (5), partial (12)]. Patients died 66 months (16-176) after the first sign of vasculitis. Main causes of death were [multiple for 6 patients]: infection (38%) [pulmonary (3), skin (2), digestive (3)], chronic liver disease (32%) [cirrhosis (2), gastrointestinal bleeding (1)], hepatocarcinoma (4), cardiovascular (18%) [myocardial infarction, pulmonary oedema, sudden death], vasculitis (18%) [cerebral, gastrointestinal], end stage renal failure (9%) and cancer (9%) [T cell lymphoma, lung]. In multivariate analysis, two factors were associated with the risk of death, i.e. a central nervous system involvement [HR=7.1; 95%CI 1.8-28.4; p=0.006], and immunosuppressors use [HR=4.4; 95%CI 1.8-10.8; p=0.001], whereas a good virological response to HCV treatment at month3 was protective [HR=0.4; 95%CI 0.1-0.9; p=0.04]. Conclusion: Death in patients presenting with HCV MC vasculitis is mainly due to infection, chronic liver disease, cardiovascular disease, and vasculitis. The risk of death is independently associated with a central nervous system involvement and the use of immunosuppressors, whereas an HCV virological response at month3 of HCV treatment is a positive prognostic factor.

INCIDENCE OF TYPE 2 DIABETES MELLITUS AND GLUCOSE ABNORMALITIES IN TREATED PATIENTS WITH CHRONIC HEPATITIS C INFECTION: RESULTS OF A CONTROLLED FOLLOW-UP STUDY

Chiara Giordanino1, Elisabetta Bugianesi1, Antonina Smedile1, Alessia Ciancio1, Maria Lorena Abate1, Antonella Olivero1, Rinaldo Pellicano1, Maurizio Cassader2, Roberto Gambino2, Giovannina Ciccone3, Mario Rizzetto1, Giorgio M. Saracco1; 1Dep Gastroepatologia, Azienda Ospedaliera Molinette, University of Turin, Torino, Italy; 2Dep of Internal Medicine, University of Turin, Torino, Italy; 3Unità di Epidemiologia dei Tumori, Azienda Ospedaliera Molinette, Torino, Italy

Background: there is evidence that insulin resistance is an unfavourable prognostic factor in patients treated for chronic hepatitis C (CHC): incidence of type 2 diabetes mellitus (DM) and impaired fasting glucose (IFG) appear increased among patients not responding to antiviral therapy. Moreover, CHC is a high-risk condition for developing type 2 diabetes. Aim: to compare the incidence of glucose abnormalities (IFG or DM) between HCV+ patients with or without a long term virological response (LTR) after antiviral therapy. Methods: all 262 HCV+ patients enrolled by our Center in therapeutic randomised controlled trials with IFN/Peg-IFN +/- ribavirin from 1991 to 2001, whose baseline sera were stored at –80°C Celsius and who accepted to be retested, were considered. Patients with baseline diabetes or fasting blood glucose >100 mg/dl were excluded (n=38). All patients had baseline data regarding age, sex, viral load, genotype, histologic staging, glucose, cholesterol, triglycerides, BMI. Baseline insulin was measured in the stored serum and HOMA-IR was calculated. Patients were retested for transaminases, HCV-RNA, glucose, cholesterol, triglycerides; presence or absence of liver cirrhosis was detected by liver biopsy and/or liver elastography at the end of follow-up. Incidence of IFG or DM at the end of follow-up was compared between patients with LTR (HCV-RNA-negative 3 years after the end of therapy) and non-responders (NR, persistently positive HCV-RNA). Results: after a median follow-up of 8.0 years (range 3-16), the cumulative risk of DM (n=9) or IFG (n=22) among the 224 HCV+ included patients was 13.8% (95%CI=9.9-19.0), while the incidence rate (x 1000 person-years) was 18.6 (12.6-26.4). The risk was lower between LTRs (12/110, 10.9%) compared to NRs (19/114, 16.7%) (Odds Ratio, OR=0.61, CI=0.28-1.33, p=0.22). To adjust the comparison of LTRs vs NRs for potential confounders, we used a logistic regression model including baseline risk factors for diabetes and predictors of poor response (age, sex, HOMA-IR, BMI, familiarity for diabetes, HCV genotype-1, high viral load, cirrhosis). The adjusted OR for IFG or DM was 0.89 (CI=0.32-2.51, p=0.82). Other important risk factors for IFG-DMM were: age (OR=1.05 x year, CI=1.01-1.10), BMI (OR=1.21, CI=1.04-1.42) and familiarity for diabetes (OR=4.19, CI=1.77-9.95). Conclusions: after adjustment for baseline risk factors, incidence of glucose abnormalities was similar between LTRs and NRs. Our data didn’t add evidence to the hypothesis of a significantly higher incidence of diabetes among HCV patients not responding to therapy, but much larger studies are needed to exclude this possibility.

CPY1A1 POLYMORPHISM IS RELATED WITH FIBROSIS IN CHRONIC HEPATITIS C

Gloria Moraleda, Rafael Barcena, Santos del Campo; Gastroenterology, Hospital Ramon y Cajal, Madrid, Spain

Background: Hepatitis C virus (HCV) infection is a worldwide health problem. Chronic HCV is characterized by progressive liver fibrosis; progression to cirrhosis takes place over a course of 20-30 years. There is evidence that genetic factors have an important role in the progression of liver fibrosis. Among these factors, cytochrome P-450 complex of enzymes (CYPs) seem to be important. CYPs are involved in the metabolism of drugs, chemicals and endogenous substrates. Genetic polymorphism of CYPs with modified activities have been showed to be associated with pathogenesis of several liver diseases. Aim: To analyze whether the polymorphisms of CPY1A1, CPY1A2, CPY2D6 and CPY2E1 genes are associated with liver fibrosis in chronic hepatitis C infection. Patients and Methods: One hundred and twenty five patients with chronic hepatitis C were included (87 males, 38 females, mean age ± SD: 49.9 ± 10.6 years). Grade and stage of liver fibrosis was assessed according to Knodell Index, ranging from F0 to F4. Patients were divided into 2 groups: Fibrosis 0-2 (n=90) and Fibrosis 4-3 (n=35). Genomic DNA was extracted from peripheral blood and polymorphisms of the CYP genes were analyzed by polymerase chain reaction (PCR) followed by restriction fragment length polymorphism (RFLP). The presence or absence of mutant alleles was correlated with a “slow” or “fast-acetylation” phenotype, respectively. CPY1A1: m1/m2 polymorphism in the 3'-noncoding region was detected by digestion with MspI, to differentiate the wild (m1) and the mutant (m2) alleles. CPY1A2: The transversion from A to C at position 734 in the first intron of CPY1A2 gene was analyzed by digestion with Apal. The presence of A or C represent the wild or mutant phenotype, respectively. CPY2E1: The 5'-flanking region of CPY2E1 was analyzed by restriction enzyme using PstI and RsaI. CPY2D6: The mutant allele CPY2D6*4 (G to A transition at position 1934) was studied by digestion with BsNI. Results: When CPY1A1 was analyzed, the frequency of wild-type and mutant alleles in group F0-2 was 85.5% (77/90) and 14.5% (13/90), while in group F3-4 was 63% (22/35) and 37% (13/35), respectively. The frequency of mutant phenotype was significantly higher in the F3-4 group when compared with F0-2 group (14.5 % vs 37%, p<0.007). When CPY1A1, CPY2E1 and CPY2D6 were analyzed, no differences between groups were obtained Conclusion: This preliminary results show an association between slow-acetylation status of CPY1A1 and liver fibrosis in chronic hepatitis C infection.

COMPARISON OF TWO REAL-TIME PCR BASED ASSAYS (REALTIME HCV, COBAS TAQMAN) WITH A SIGNAL AMPLIFICATION ASSAY (BDNA) FOR HCV RNA DETECTION

Johannes Vermehren1, Anette Wohnsland1, Barbara Gärtner2, Annegret Otto, He-Jun Yuan3, Nahid Attar1, William M. Lee1; 1Internal Medicine, University of Texas Southwestern, Dallas, TX; 2Makerere Medical School, Kampala, Uganda; 3Johns Hopkins University, Baltimore, MD

Background: The prevalence of hepatitis C virus (HCV) infection in Africa varies between countries and communities. For most clinical testing currently in Uganda, commercially available rapid slide assays (RSA) are used to detect anti-HCV, rather than enzyme immunoassays (EIA). We determined the prevalence of HCV and the accuracy of these two testing modalities among patients admitted to a large city emergency medical ward (EMW) in Uganda. Methods: 380 patients admitted consecutively to Mulago Hospital, Kampala, were recruited after informed consent. Sera were tested for anti-HCV antibodies in Kampala using a Rapidtest® slide assay (Cortez Diagnostics, Calabasas, CA) and sent frozen to Dallas for blinded re-testing: anti-HCV antibodies by EIA and nucleic acid testing (NAT) (Siemens Centaur® and Versant® bDNA 3.0 respectively, Siemens Diagnostics, Tarrytown, NY), followed by polymerase time RT-PCR based tests have been introduced in routine diagnostics recently and have the potential of highly sensitive detection together with accurate quantification of HCV RNA in one assay. However, despite standardization to international units significant differences have been described between commercially available assays for HCV RNA quantification. Methods: In the present study, a new real-time PCR based assay (Abbott Realtime HCV, Abbott Molecular) was compared to the COBAS AmpliPrep/COBAS TaqMan HCV test (CAP/CTM, Roche Molecular Systems), and a signal amplification based assay (bDNA, Versant HCV Quantitative, Siemens). Results: Correlation of HCV RNA concentrations between the three different assays was estimated on repetitive testing of 66 clinical samples of patients infected with HCV genotypes 1 to 5. For the different HCV genotypes (gt) RealTime HCV showed mean differences of 0.02 (gt1a/b), 0.22 (gt2), 0.27 (gt3), 0.19 (gt4), and 0.03 (gt5) log10 IU/mL HCV RNA in comparison to bDNA and -0.75 (gt1a/b), -0.14 (gt2), 0.24 (gt3), 1.27 (gt4), -0.09 (gt5) log10 IU/mL HCV RNA. Genotype-specific assay sensitivity was estimated for RealTime HCV and CAP/CTM by multiple testing of HCV RNA concentrations between 3 and 50 IU/ml derived from diluted clinical samples. RealTime HCV showed a lower detection limit of 11.5 (gt1), 9.7 (gt2), 4.5 (gt3), 18.2 (gt4), and 3.6 (gt5) IU/ml whereas the lower detection limit for CAP/CTM was 14.5 (gt1), 46.8 (gt2), 29.2 (gt3), 56.3 (gt4), and 8.6 (gt5) IU/ml. For RealTime HCV, CAP/CTM, and bDNA HCV RNA quantification was linear between 4x10³ and 1x10¹⁰ IU/ml, with a correlation coefficient between expected and observed results of >0.98. Conclusion: In conclusion, highly sensitive detection and reliable HCV RNA quantification was observed for RealTime HCV, CAP/CTM, and the bDNA assay. However, up to 5-fold differences of absolute quantification were detected between the assays in genotype 1 infected patients which may cause significant problems for selection of patients suitable for treatment shortening.

Disclosures: The following people have nothing to disclose: Johannes Vermehren, Anette Wohnsland, Barbara Gärtner, Annegret Otto, Reinhold Gobel, Stefan Zeuzem, Christoph Sarrazin

chain reaction (PCR) for bDNA negative samples. Recombinant immunoblot assay (RIBA) was used for NAT-negative samples. Anti-HCV antibody negative samples did not have NAT. Genotyping was determined after direct sequencing. Results: 49 patients (12.9%) were anti-HCV positive (n=43) or equivocal (n=6) by one or both methods. However, prevalence of anti-HCV antibodies was 5% and 6.8% by RSA and EIA respectively, showing very low concordance between the methods (only 3/49 positive in both tests; all 3 NAT positive). Of 16 RSA pos Kampala, but neg by EIA in Dallas, 3 were NAT pos, none were RIBA pos. Of 23 EIA pos in Dallas but RSA neg in Kampala, 5 were NAT pos; 2 were RIBA pos but NAT neg. RIBA testing performed on 32/49 HCV antibody positives revealed only 2/32 RIBA positive tests. 11/11 tested were genotype 1a. Summary: In this in-hospital prevalence study, 49/380 patients tested anti-HCV positive, but only 13/380 (3.4%) were NAT positive. Conclusions: Antibody testing yielded many apparent false positives using either RSA or EIA, with little overlap; rare false negatives were also observed. Previous studies in Africa have shown high false positive rates for anti-HCV, cause unknown, but presumably unique to this patient population and possibly due to cross-reactive antibodies with another flavivirus(es). These data indicate that the majority of reactive anti-HCV results are false positive. If confirmed in other sub-Saharan countries, the findings underscore the importance of confirmatory testing when establishing the diagnosis of chronic hepatitis C. Supported in part by James and Alinda Wikert Fund of the Southwestern Medical Foundation, Dallas TX and with lab support from Siemens Diagnostics, Tarrytown NY.

1365 FIBROSIS STAGES DETERMINATION, REPRODUCIBILITY AND ROBUSTNESS OF BLOOD TESTS FOR LIVER FIBROSIS IN CHRONIC HEPATITIS C
Paul Cales1,2, Philippe Halff3, Yannick Bacq3, Vincent Leray4, Marie Christine Rousselet5, Marc Bourlière6, Anne de Muret7, Nathalie Sturm8, Gilles Hunault9, Guillaume Penaranda2, Marie Claude Brechot10, Candidce Trocme11, Jerome Bouruis12, 1Hepatology, University hospital, Angers, France; 2University Hospital, Grenoble, France; 3Alphablo, Marseille, France; 4Hepatology, University hospital, Tours, France; 5Pathology, University hospital, Angers, France; 6Hepatology, University hospital, Grenoble, France; 7Pathology, University hospital, Angers, France; 8Hepatology, University hospital, Tours, France; 9Biochimie, University hospital, Grenoble, France; 10HIFA laboratory, University hospital, Angers, France; 11University Hospital, Angers, France; 12Biochimie, Hospital, Tours, France

Aims. We evaluated new statistical tests describing the performance and reproducibility, including robustness, of blood test for liver fibrosis. Methods. Four blood tests were measured in 825 patients with chronic hepatitis C and liver biopsy. New statistical indices were: fibrosis stage probability for a precise diagnostic performance; reproducibility was evaluated with the overall reproducibility test index and 4 tests of robustness. Results. Performance - The fibrosis stage probability provides the percent chance of Metavir fibrosis stages as a function of its blood test value. The blood test can be divided into new bracket of fibrosis staging according to maximum probability. This graphic metric provides a new classification of fibrosis according to blood test stages. Reproducibility - The overall reproducibility is based on the coefficient of variation for the diagnostic cut-offs of blood tests among centers: FibroMeter: 4.2%, APRI: 24.0%, Fibrotest: 24.2%, Hepascore: 35.0%. The following indices evaluate the blood test robustness. Using published regression scores, the calculated a posteriori cut-offs and corresponding overall accuracy (gain against baseline a priori cut-offs) were in the whole population, respectively: FibroMeter: 0.51, 77.5% (0.8%), Fibrotest: 0.43, 74.1% (2.0%), Hepascore: 0.47, 72.7% (0.5%), APRI: 0.55 (vs 1.0), 73.9% (6.1%). The proportion of patients where the diagnosis of significant fibrosis consequently changed was: FibroMeter: 0.8% (p<0.02 vs baseline), Fibrotest: 5.8% (p=10-3 vs baseline and FibroMeter), Hepascore: 2.4% (p<10-3 vs baseline and p=0.02 vs FibroMeter), APRI: 18.2% (p=10-3 vs baseline and FibroMeter). The performance of new regression scores, calculated in the whole population, significantly increased compared to that of original-published-scores whereas the number of independent variables decreased for Fibrotest and Hepascore. The performance and the number of independent variables of FibroMeter were stable. The inclusion of all variables of all blood tests in stepwise binary logistic regression provided a new score for significant fibrosis including all the 7 variables of FibroMeter combined with sex (AUROC gain: 0.007) yielding an overall accuracy of 76.1% and an AUROC of 0.856 (p=0.02 vs FibroMeter). Conclusion. The fibrosis stage probability provides a new classification of fibrosis stages. The overall reproducibility test index offers the advantage of combining all the sources of variability. Thus, this is a global evaluation of the clinical applicability of a test. FibroMeter is the only test with a minimal variation in diagnostic performance and cut-off together with the highest robustness.

eral reference population, matched for clinical and epidemiological features. By multivariate analysis, a reduced HRQOL was independently associated with a history of medical treatment against depression (low mental and physical summary scores of SF-36). A low physical summary score was associated with low working ability, whereas a low mental summary score was associated with age, IVDU and low social ability. HADS anxiety and depression scores were independently associated with a history of depression, low social and working ability. None of the SF-36 or HADS scores correlated with different levels of viral load or viral presence/absence. In particular, when comparing patients HCV RNA+ (n=555; 295 treatment naïve, 260 non-responders or responders-relapers to antiviral therapy) with those who did not have a detectable viral load (n=262; 42 with spontaneous clearance and 220 with sustained virological response in whom viral load was assessed ≥24 weeks after the end of treatment), we did not find any significant differences regarding any SF-36 or HADS scores between HCV RNA+ and HCV RNA- patients. In conclusion, anti-HCV+ persons have decreased HRQOL compared to controls. However, host and environmental factors, rather than viral, seem to impact on HRQOL level.

**THE APRI CAN NEGATIVELY PREDICT CIRRHOSIS IN PATIENTS WITH CHRONIC HEPATITIS C (HCV)**

Ned Snyder1, Rami Hawari1, Shu-Yuan Xiao2, John Petersen2; 1Internal Medicine, University of Texas Medical Branch, Galveston, TX; 2Pathology, University of Texas Medical Branch, Galveston, TX

Background: Radiologic screening for hepatocellular cancer in patients with HCV related cirrhosis is recommended. However, not all patients with HCV receive a liver biopsy, and the fibrosis stage of many patients is unclear. Several hepatitis fibrosis markers have been shown to be effective in separating mild from significant fibrosis in about 40-60% of patients, they are not as useful for predicting cirrhosis. We have previously found the AST Platelet Ratio Index (APRI) to be quite accurate in predicting mild and significant fibrosis, but there is overlap between F2-F4. (J Clin Gastroenter 40:535).

**Purpose:** We wanted to determine if the APRI could be used as a negative predictor of cirrhosis, and if so, what would be the best cut-off.

**Methods:** The patients studied are enrolled in a prospective study of hepatitis fibrosis markers in patients undergoing pretreatment staging liver biopsies for HCV. Blood was drawn on the day of the biopsy. The biopsies were read blindly by one pathologist using the Batts Ludwig criteria (F0-F4). The APRI was calculated as below*.

**Results:** 277 patients were studied, and 49 (17.7%) had cirrhosis while 88 (31.8%) had advanced fibrosis (F3-F4). The results are summarized in the table below. A cut-off of 0.54 correctly identified all 49 patients with F4 for a NPV of 100%, while a cut-off of 0.78 correctly identified 45 of 49 for an NPV of 97.0%. Using a cut-off of 0.78, unnecessary screening could have been avoided in 128 of the 228 patients (56.1%) without cirrhosis. A cut off of 0.54 identified 82 of 88 patients with advanced fibrosis for a NPV of 96.6%.

**Conclusion:** The APRI could be used to screen for patients with HCV that are unlikely to have cirrhosis, and therefore do not need screening for hepatocellular carcinoma.

**PROSPECTIVE COMPARISON OF TWO COMMERCIAL NON-INVASIVE FIBROSIS SERUM MARKER PANELS (FIBROSURE AND FIBROSPECT II) DURING INTERFERON-BASED COMBINATION THERAPY IN CHRONIC HCV GENOTYPE 1**

Keyur Patel1, Yves Benhamou2, Eric M. Yoshida3, Kelly D. Kaita4, Stefan Zeuzem5, Michael Torbenson6, Erik Pulkstenis7, John G. McTutchinson1, G M. Subramanian7; 1Duke Clinical Research Institute, Durham, MD; 2Hopital Pitie-Salpetriere, Paris, France; 3University of British Columbia, Vancouver, BC, Canada; 4University of Manitoba, Winnipeg, MB, Canada; 5W. Goethe-University Hospital, Frankfurt, Germany; 6Johns Hopkins University, Baltimore, MD; 7Human Genome Sciences, Rockville, MD

Background/Aim Noninvasive methods that follow changes in liver fibrosis after antiviral therapy could provide an alternative to liver biopsy for assessment of secondary histologic endpoints for CHC patients. Methods Comparisons between the two commercially available HCV fibrosis serum marker panels in the US (HCV FibroSure (Labcorp, Burlington, NC) and FibroSpect II (Prometheus Laboratories, San Diego, CA) were independently evaluated in serum samples obtained pre-treatment and at various intervals during the study (w12, 24, 48 on treatment and w12 and 24 follow up) in a Phase 2b, study of albinterferon alfa-2b or Peginterferon combination treatment in genotype 1 CHC, IFN-naïve patients. Pre-treatment liver biopsy specimens were graded for METAVIR fibrosis by a single pathologist. Results Pre-treatment serum marker panel tests were evaluated in 95 CHC patients (FibroSpect II, n=92; FibroSure, n=84), with mean biopsy length of 17.8 ± 8.0 mm and a prevalence of F2-F4=23% (22/95). Both panels indicated a very high sensitivity (FibroSure=1.00; FibroSpect II=0.95) in detecting stage F2-F4, a lower but comparable specificity (FibroSure=0.61; FibroSpect II=0.66), and a good AUROC (0.89 for FibroSure and 0.90 for FibroSpect). More notable changes were observed with FibroSpect II during therapy (panel A). Patients with SVR (n=45/68; 66.2%) had a trend towards greater improvement in index scores for both FibroSure (2.94 v. -20; p=0.14) and FibroSpect II (18.44 v. -6.82, p=0.05) (panel B). Conclusions Both marker panels demonstrate comparable performance characteristics for differentiating CHC patients with moderate-to-severe stage disease at baseline. Trends toward improvement in regression index scores with SVR suggest an improvement in liver fibrosis, and indicate the potential utility of non-invasive markers in assessing change in fibrosis with treatment.

A PRACTICAL INDEX (FIBROINDEX) FOR THE PREDICTION OF SIGNIFICANT FIBROSIS IN PATIENTS WITH CHRONIC HEPATITIS C
Masahiko Koda, Yoshikazu Murawaki; 2nd Department of Internal Medicine, Tottori University, Yonago, Japan
The diagnosis of liver fibrosis stage in chronic hepatitis C is essential for prognostication and decision on antiviral therapy. This study constructed a simple model consisting of routine laboratory tests, then validated the model in cross-sectional and longitudinal studies. Consecutive treatment-naïve patients with chronic hepatitis C who underwent liver biopsy were divided into 2 cohorts: estimation set (n=240) and validation set (n=120). Longitudinal set consisted of 30 patients who underwent liver biopsies twice, before and after IFN treatment. FibroIndex was derived from platelet count, AST and gamma-globulin in the estimation set. The areas under the ROC curves of FibroIndex for the prediction of significant fibrosis were 0.83 and 0.82 for the validation set and better than those of Forns’ index and APRI. Using the best cut off values, the presence and absence of significant fibrosis were diagnosed with high positive predictive values and 35% of patients could avoid liver biopsy. In the longitudinal set, there was a significant decrease in FibroIndex among 14 patients whose fibrosis stage improved and a significant increase among 5 patients whose fibrosis stage deteriorated. Changes in the FibroIndex correlated significantly with variations in fibrosis stage. There was no such correlation for Forns’ index or APRI. In conclusion, FibroIndex is a simple and reliable index for the prediction of significant fibrosis in chronic hepatitis C, and could also be used as a surrogate marker during antifibrotic treatment for chronic hepatitis C.

ANTI-ARFP ANTIBODY POSITIVITY IS SIGNIFICANTLY ASSOCIATED WITH INCREASED HCV VIRAL LOAD IN END STAGE LIVER DISEASE
Jose L. Walewski1, Julio A. Gutierrez1, Arielle L. Klepper1, Ileana Aderca1, Michael R. Charlton2, Lewis R. Roberts2, Andrea D. Branch3; 1Liver Unit, Dept. of Gastroenterology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; 2Cell Research and Immunology, Tel Aviv University, Tel Aviv, Israel
Intro: ARFPs stimulate specific immune responses in patients, but their functions are unknown. Because antibody levels can reflect disease states, (Nishizono, 1993; Baumert, 2000), we have developed a novel, specific and sensitive indirect ELISA for anti-ARFP antibodies in patient serum, seeking evidence of associations between anti-ARFP antibody levels and clinical parameters such as viral load, or presence of HCC. Synthetic core and ARFP peptides were used throughout. Methods: Serum samples were collected under Mayo Clinic or MSSM IRB approved consent. 1a Core peptide (aa 7-25), ARFP 1a consensus 70 mer peptide (aa 1-70) and ARFP middle peptide (aa71-89) were covalently linked to Reacti-Bind Maleimide Activated plates (Pierce). Serum samples were tested at a 1:2,000 dilution. All samples were measured in duplicate on each assay date, these values were averaged and BSA (ARFP 70mer) or PDCE2 (Core and middle ARFP) background values were subtracted. Threshold for positivity was the mean plus 3 St Devs. of 10 end-stage liver disease (ESLD) patients. 39 HCV ESLD samples were tested on each peptide. To be anti-ARFP positive, a sample had to test positive for both peptides (70mer and middle), both times each sample was tested. Statistical analyses were run in JMP 5.1. Results: All negative controls were negative for reactivity to core, 1a amino and middle ARFP peptides. There was no difference in anti-core positivity between the ARFP negative or positive samples. However, ARFP positivity was associated with a significantly higher HCV viremia, with log10 values of 1.71 +/- 0.43 in the ARFP negative samples, versus 3.53 +/- 0.73 (mean +/- SE) in the ARFP positive samples. This difference was statistically significant, p=0.026 by Wilcoxon Rank Sums test. Conclusions: While HCV ESLD were equally positive to core, ARFP positivity was significantly associated with higher HCV viremia in the ESLD. These results indicate that expression of the ARFP by HCV may vary by viral load, and that the detection of antibodies to this protein may provide clinically useful information regarding viral load to further evaluate patient status. (Supported by NIDA016156 and DDK066939)

SERUM LEVELS OF ASIALOGLYCOPROTEIN RECEPTOR SH2A CORRELATE WITH SUCCESS OF TREATMENT OF HCV PATIENTS
Yoav Lurie1, Elena Veselkin2, Maria Kondratyev2, Efrat Ron2, Moshe Santo1, Shimon Reif1, Irma Elashvili1, Lana Bar1, Ran Oren2, Gerardo Z. Lederkremer2; 1Liver Unit, Dept. of Gastroenterology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; 2Cell Research and Immunology, Tel Aviv University, Tel Aviv, Israel
Study’s purpose: Using a novel sensitive marker of liver function, a soluble secreted form of the human asialoglycoprotein receptor (ASGPR sh2A) (see accompanying abstract) we have done a longitudinal study of therapeutic success of HCV patients. sh2A is secreted to the serum exclusively by hepatocytes and thus its levels reflect their functional state. Methods: Retrospective double blind study of serum samples analyzed for routine liver markers compared to sh2A, measured with a newly-developed ELISA assay. Results: A cohort of 17 HCV patients with mild fibrosis, followed monthly or biweekly during a year of treatment with ribavirin and interferon alpha showed a clear correlation of successful therapy (as measured through PCR to determine viral clearance) with a rapid recovery of sh2A to normal levels. In the cases where the therapy was not successful, sh2A levels remained abnormal or oscillated. In contrast, alanine and aspartate aminotransferases (ALT and AST) returned to normal values in all cases, as the treatment corrected the immediate causes of liver damage (reflected by the secretion of these enzymes) but did not necessarily lead to full...
recovery of hepatocyte function. Indeed, when sH2a levels returned to normal, this took place with a lag of 2-3 weeks after recovery of ALT to normal levels, as the recovery of hepatocyte function ensued reduction in damage. Albumin, prothrombin time and alkaline phosphatase show abnormal levels only for advanced disease and appeared normal throughout the treatment for almost all these mild patients. Conclusions: sH2a appears to be a unique sensitive marker, which could be well-suited for the non-invasive follow up of recovery of liver function in the course of therapy of HCV patients.

1372  INFLUENCE OF INTERFERON (IFN)-BASED THERAPY ON LIVER FIBROSIS PROGRESSION (LFP) IN HIV/HCV CO-INFECTED PATIENTS
Yves Benhamou¹, Marc Antoine Valentín², ³, Stéphanie Dominguez, Marina Varastel, Adelina Zin, Christine Kattama², Thierry Poynard¹; ¹Hepatology, Hôpital Pitié-Salpêtrière, Paris, France; ²Infectious Diseases, Hôpital Pitié Salpêtrière, Paris, France; ³ClinSearch, ClinSearch, Bagneux, France

Background: LFP is more rapid in HIV/HCV co-infected patients compared to HCV mono-infected patients. The impact of IFN-based therapy on LFP in real life has been poorly studied in co-infected patients. Objective: To study impact of IFN-based therapy on LFP in HIV/HCV co-infected patients. Methods The data of all HIV/HCV co-infected patients who had undergone two liver biopsies were extracted from a cohort of HIV/HCV co-infected patients followed-up in our center. Patients who received IFN-based therapy were compared to those who never received anti-HCV therapy using the Chi-2 or Fisher’s exact test. Results The HIV/HCV co-infected cohort included 437 patients (75% male), aged 35±8 yrs at first visit: 230 patients had received anti-HCV therapy (≥3 months, mainly peginterferon plus ribavirin), 207 did not. Liver biopsy (METAVIR) results were available in 187 (81%) and 114 (55%) of the treated and untreated patients, respectively. Hepatitis C was more severe in the treated vs. untreated group: liver activity was graded A2/A3 in 51% vs. 22% (p<0.001) and fibrosis was scored F3/F4 in 38% vs. 13% (p<0.001) of the cases at the first biopsy. LFP was evaluated in 44% of treated patients and 14% of untreated patients who had repeated biopsies (table). The median time from first to last biopsy was 3.9 and 4.3 years, respectively (p=0.858). The LFP rate, expressed in METAVIR F points per year, was lower in treated patients achieving a sustained virological response (SVR) to anti-HCV therapy compared to patients with no SVR and untreated patients (p=0.024). Treated patients had a reduced LFP rate compared to untreated patients (0.18±0.59 vs. 0.22±0.46). Patients with SVR had a negative mean LFP rate indicating regression of fibrosis. Conclusion Anti-HCV therapy in HIV/HCV co-infected patients tended to slow down liver fibrosis progression and was associated with liver fibrosis improvement in patients achieving a SVR. Near half of the untreated patients with mild liver fibrosis at baseline may have at least 1 point worsening in liver fibrosis after a median period of 4 years. This research was supported by Schering Plough.

1373  HIGHER LEVEL OF ALANINE AMINOTRANSFERASE MASS IN LIVER DISEASE PATIENTS THAN NORMAL POPULATION MEASURED BY SANDWICH ELISA
Eui Y. Choi¹, Hyun-Jung Kim¹, Dong J. Kim², Kyung-Joon Kang¹, Se-Hyun Bang¹, Sang W. Oh²; ¹Biomedical Sciences, Hallym University, Chuncheon, South Korea; ²Internal Medicine, Hallym University, Chuncheon, South Korea; ³Biology Education, Chunbuk University, Chunju, South Korea

Alanine aminotransferase (ALT1, GPT) mediates the reversible transamination between alanine and alpha-keto-glutarate to form pyruvate and glutamate, and it has been used clinically as an indicator of liver function test. However, the catalytic activity of this enzyme is not corresponded well to a degree of hepatocellular damage. To resolve this issue, we developed an immunoassay procedure for measurement of ALT1 mass. ALT1 cDNA was amplified by RT-PCR from human liver mRNA and cloned into an expression vector. Recombinant ALT1 protein was produced in a bacterial expression system and injected for the production of monoclonal antibodies (mAbs) against ALT1. After selection of mAb pairs by epitope mapping, we fabricated a sandwich ELISA system. ALT1 mass with sera from patients of liver diseases was compared to that of ALT1 enzymatic activity and analyzed for clinical use by applying to ROC curve. The enzymatic activity assay, as expected, discriminated well acute hepatitis (N=46, 789.4±1080.2 IU/L) from normal (N=30, 21.5±10.6 IU/L), but not other diseases including liver cirrhosis (N=61, 25.9±31.2 IU/L). To the contrary, the ALT1 immunoassay did show a much difference between normal group (70±31.8 ng/ml) and patient groups, particularly liver cirrhosis group (276.5±297.9 ng/ml). It suggested that the ALT1 immunoassay by mass is a more accurate diagnostic method than the enzymatic activity assay in discriminating liver disease patient from normal, particularly liver cirrhosis. And, we also measured the mass of autoantibody from the serum with each liver disease by indirect ELISA method to check whether autoantibody affects on the measurement of enzymatic activity. A higher concentration of both IgA-free and IgA-complex autoantibody were detected in serum of liver cirrhosis than that of acute hepatitis, indicating that the enzymatic activity of ALT1 in hepatocarcinoma and liver cirrhosis could be inhibited by the autoantibody. The presented results showed that the immunological measurement for ALT1 mass can be an excellent tool in establishing of discernible clinical test for patients of liver diseases.

### IN VIVO DETECTION OF CASPASE ACTIVITY IN PATIENTS WITH CHRONIC HEPATITIS C AS A NOVEL BIOMARKER OF DISEASE SEVERITY

Hesham M. Elgouhari1, Nizar N. Zein1, Ibrahim A. Hanouneh2, Lisa M. Yerian3, Rocio Lopez4, Ariel E. Feldstein1; 1Gastroenterology and Hepatology, Cleveland Clinic foundation, Cleveland, OH; 2Internal Medicine, Cleveland Clinic, Cleveland, OH; 3Anatomic Pathology, Cleveland Clinic, Cleveland, OH; 4Quantitative Health Science, Cleveland Clinic, Cleveland, OH

Background: Assessment of liver fibrosis in patients with hepatitis C infection (HCV) is currently critical for further management decision. We have recently demonstrated that determination of caspase 3-generated cytokeratin 18 (CK-18) fragments’ level in blood is an independent predictor of advanced fibrosis in patients with nonalcoholic steatohepatitis. While others have shown that these levels may be increased in patients with HCV. Thus the aim of the present study was to determine the value of this novel biomarker for assessing fibrosis in patients with HCV. Methods: Prospectively, 72 consecutive HCV-infected patients referred to our liver biopsy clinic were enrolled. On the biopsy day, demographic and clinical data were collected along with blood samples. Histology of all liver biopsies was assessed blindly by an experienced hepatopathologist and used as the gold standard method for fibrosis staging using the Batts-Ludwig scoring system. CK-18 fragments’ level was measured in duplicates using a specific sandwich immunoELISA assay. Results: CK-18 fragments’ level was high in patients with advanced fibrosis (Stage 3-4, n=16) compared to those without advanced fibrosis (Stage 0-2, n=56) (Median (Q25, Q75): 276 U/L (146, 559), 168 U/L (96, 343)) respectively, although the difference did not reach statistical significance (P =0.08). The odds of having advanced fibrosis increased with increasing CK-18 levels. For every 50 U/L increase in the plasma level of CK-18 fragments, the likelihood of having advanced fibrosis increased 10%. In multivariate analysis, CK-18 fragments’ level was found to be marginally associated with advanced fibrosis (P = 0.054) after adjusting for several factors including age and presence of steatosis. Conclusion: Measurement of plasma CK-18 fragment level appears to be useful to identify HCV patients with severe fibrosis. Future larger studies are warranted.

### COMMON PATHWAYS IN ENDOGENOUS DEPRESSION AND IN IFN-INDUCED DEPRESSION IN HCV PATIENTS

Martin Trippler1, Bo Wang1, Yesim Erim2, Sabine Bein1, Norbert Scherbaum3, Guido Gerken4, Joerg F. Schlaak1; 1Dept. of Gastroenterology and Hepatology, University Hospital of Essen, Essen, Germany; 2Dept. of Psychosomatics, Rheinische Kliniken, Essen, Germany; 3Dept. of Psychiatry and Psychotherapy, Rheinische Kliniken, Essen, Germany

Aims and background: Combination therapy with pegylated interferon-alpha (IFN-α) and ribavirin for chronic hepatitis C can induce depressive side effects in up to one third of patients. To date, it is unclear if IFN-induced depression and endogenous depression have common causes. Patients and methods: A total of 50 Caucasian patients with histologically proven chronic hepatitis C were treated with standard combination therapy consisting of pegylated IFN-α2a (Pegasys, 180µg once weekly) and ribavirin (800-1200 mg daily) for 6 or 12 months. RNA was isolated from peripheral blood which was collected 12h before and 12h after the first injection of IFN-α. The transcriptional profile was analysed using human genomic microarrays (Affymetrix, HG U133A) and quantitative real-time RT-PCR. Array data were normalized and fold change values were subjected to class prediction analysis to identify genes which are differentially regulated in patients with or without IFN-induced depression. Furthermore, PBMC from 10 HCV-negative patients hospitalized for severe major depression and from 11 healthy controls were cultivated in vitro with (100 and 1.000 U/mL) or without pegylated IFN-α2a for 16h to assess the expression of target genes using quantitative RT-PCR. Results: 11/50 HCV patients (22%) developed clinically relevant IFN-induced depression. Using class prediction analysis, the development of depression could be predicted with 91% accuracy by 16 genes which were significantly higher induced in patients with IFN-associated depression compared to patients without depression during IFN treatment. Interestingly, 6 of these genes (DYNLT1, GCH1, TOR1B, DISC1, MEF2A, ST3GALS) have previously been described as being associated with recurrent major depression or with neuronal development in the brain, whereas the remaining genes were identified as classical IFN response genes. These data could be verified by quantitative RT-PCR. After in vitro IFN stimulation the gene response of 5/6 depression-associated genes was significantly higher in PBMC from 10 patients hospitalized for severe major depression as compared to 11 healthy controls. Conclusions: These data suggest that selective hyper-responsiveness to exogenous IFN therapy or endogenous (endogenous depression) type 1 IFNs may lead to the development of depressive symptoms. The functional analysis of the differentially regulated target genes that were identified in this study could lead to the discovery of novel therapeutic approaches to improve the efficacy of and adherence to HCV therapy and, possibly, to treat major endogenous depression.

Differential pattern of HCV-specific T cell responses distinguishes SVR and relapse patients receiving standard antiviral therapy plus therapeutic IC41 vaccination

Heiner Wedemeyer1, Erich Tauber2, Elisabeth Schuller2, Johannes Wiegand8, Ingolf Schiefele8, Wolf-Peter Hofmann5, Stefan Zeuzem5, Holger Hinrichsen5, Mark R. Thursz4, Bernd Jilma1, Rudolf E. Stauber2, Michael P. Manns1, Christoph S. Klade8; 1Center for Internal Medicine, Hannover Medical School, Hannover, Germany; 2Intercell AG, Vienna, Austria; 3Department of Clinical Pharmacology, Medical University of Vienna, Vienna, Austria; 4Faculty of Medicine, Imperial College, London, United Kingdom; 5Internal Medicine II, Saarland University Hospital, Homburg/Saar, Germany; 6Medizinische Klinik 1, Universitätsklinik Schleswig-Holstein [UK SH], Kiel, Germany; 7Medical University Graz, Graz, Austria; 8Medizinische Klinik und Poliklinik II, Universitätsklinikum Leipzig, Leipzig, Germany

Virological relapse after end of therapy is observed in 20-40% of patients responding to PEG-IFN/RBV based standard therapy (ST) of chronic hepatitis C. Enhancing HCV-specific T cell responses by therapeutic vaccination might be an option to prevent relapse. However, effects of ongoing ST on vaccine responses are largely unknown. IC41 consists of five synthetic peptides harboring HCV T-cell epitopes and the synthetic adjuvant poly-L-arginine. IC41 can induce HCV-specific IFN-gamma-secreting CD4+ and CD8+ T cells in healthy volunteers and chronic HCV patients refractory to ST. Here we aimed to investigate IC41 during ST and its ability to reduce relapse rates in an open label, single arm phase II study. 35 patients with chronic HCV genotype 1, HCV-RNA-negative (Cobas Amplicor test, detection limit 100 copies/ml) after 12 weeks of ST received 6 s.c. vaccinations of IC41 in 4 weeks intervals from ST-week 28 to 48. HCV peptide-specific T cell responses were assessed at treatment weeks 28 (prior first vaccination), 48, FU-4, FU-12 and FU-24 applying IFN-gamma ELISPOT, proliferation and HLA-A2 tetramer assays. From 23 patients fulfilling all criteria of the study protocol (HLA-A2 positive, RNA negative at week 48), 14 achieved SVR, whereas 8 relapsed (36%), for 1 patient follow-up data were missing. T cell responses were weak or absent at week 28 before vaccination and were significantly more frequent and stronger at the end of antiviral therapy and during follow-up in 8/23 patients. Interestingly, we found a clear-cut difference between patients who relapsed and patients with SVR in terms of ELISPOT at weeks 48 and FU-4: while T cells were barely detectable in relaper, over 40% of SVR patients showed robust T cell responses against the vaccine peptides. Finally, ELISPOT response rates and strength were compared to previous studies applying the same vaccine dose and schedule in healthy volunteers (n=120) and chronic non-responder/relaps patients (N=60). Patients in the current trial (HCV-RNA negative and receiving interferon therapy) had slightly higher T cell response rates as compared to RNA-positive nonresponders patients, matching closely response rates in healthy volunteers. In conclusion, IC41 vaccination did not prevent virological relapse in patients receiving standard PEG-IFN/ribavirin therapy of chronic hepatitis C. However, T cell responses were inducible in individuals with ongoing interferon treatment and these T cell responses were associated with lower relapse rates. Future trials need to explore whether optimized vaccine responses may enhance sustained response rates to standard therapy of chronic hepatitis C.

A phase 1 study to evaluate the safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of escalating single doses of R7025, a novel pegylated interferon α compared to placebo and peginterferon α2a (40KD) (PEGASYS®) in healthy volunteers

Barbara Brennan1, Richard Robson2, Ignacio Rodriguez3, Julian Symons5, Jane Huang3, Margaret Chan1, Steven Blotner1, Natanya Jennings1, Bina Rawal3, Michael Brunda4, Greg Hooper4, Ashok Rakshit1, Roche, Nutley, NJ; 2Christchurch Clinical Studies Trust, Christchurch, New Zealand; 3Roche, Palo Alto, CA; 4Roche, Welwyn, United Kingdom

Background: Pegylated interferon (PEG-IFN) in combination with ribavirin is the standard of care for patients with chronic hepatitis C (CHC). However, treatment is not yet optimal in patients infected with HCV genotype 1 with sustained viral response rates of ~50%. R7025 is a novel human pegylated IFNα molecule generated using DNA Shuffling (Maxygen, Inc.) technology that exhibits ~50-fold higher antiviral activity compared to PEG-IFNα-2a, but only 2- to 10 fold greater antiproliferative activity in vitro. R7025 contains the identical branched chain 40KD PEG molecule used in the synthesis of PEG-IFNα-2a. The primary objective of this study was to evaluate the safety, tolerability, PK and PD activity of single ascending doses of R7025 in healthy volunteers. Methods: In each cohort, subjects were randomized to receive a single dose administered subcutaneously in the abdomen according to the following scheme: 8 R7025, 2 placebo, 2,180 µg PEG IFNα-2a. Subjects were evaluated frequently for safety, tolerability, PK and PD assessments. The following dose levels were evaluated: 1, 5, 20, 40, 80 and 120 µg. Results: 72 subjects were enrolled and completed the study. The PD markers, serum neopterin and 2′,5′-oligoadenylate synthetase (2,5 OAS) levels were increased in subjects who received a 20-120 µg dose of R7025. Doses of 40 µg and higher produced a similar level of PD induction as a 180 µg dose of PEG IFNα-2a. Serum exposure (Cmax and AUC) of R7025 increased with dose and was sustained over 168 hrs, supporting a minimum of once weekly dosing. Doses up to 80 µg were well tolerated with most adverse events rated (AEs) as mild or moderate. No serious AEs have been reported. In the 120 µg group, 4/8 R7025 treated subjects experienced severe flu-like symptoms, which were adequately controlled with analgesics and fully reversible. Most subjects who received 20-120 µg of R7025/placebo exhibited a reversible decrease in neutrophils but only grade 1/2 changes in neutrophils were observed. Conclusion: R7025 doses up to 80 µg were well tolerated with 20 µg being the lowest pharmacologically active single dose studied. R7025 doses of 40 µg and greater produced a level of serum neopterin and 2,5 OAS induction which was comparable to a 180 µg dose of PEG IFNα-2a. Most AEs were mild and consistent with those observed after administration of IFNα. A dose of 120 µg transient severe flu-like symptoms were induced in 2 of 8 patients.
observed. Changes in hematological parameters observed across all doses were mild and reversible. The findings from this study warrant further evaluation of R7025 in CHC patients.

1378 PHOSPHOROTHIOATE OLIGONUCLEOTIDE IS A POTENT ENTRY INHIBITOR OF HEPATITIS C VIRUS INFECTION IN VITRO AND IN VIVO
Takuya Matsumura1, Takenobu Kato1, Zongyi Hu1, Michio Imamura2, Nobuhiko Hiraga1, Jean-Marc Juteau3, Andrew Vaillant3, Kazuaki Chayama1, T. Jake Liang1; 1Liver Diseases Branch, National Institutes of Health, Bethesda, MD; 2Department of Medicine and Molecular Science, Division of Frontier Medical Science, Hiroshima, Japan; 3REPLICor Inc., Laval, QC, Canada

Current treatment of chronic hepatitis C based on combination of peginterferon and ribavirin is only effective in about half of the patients and is accompanied by substantial side effects. Developing new classes of drugs against HCV is crucial. Phosphorothioate oligonucleotides (PS-ONs) have a sequence-independent antiviral activity against HIV-1 by inhibiting virus-cell fusion. Because viral entry is a highly conserved mechanism, this antiviral action of PS-ONs may be effective against infection by other enveloped viruses with type I or II fusion mechanisms. The aim of this study is to assess whether PS-ONs inhibit HCV infection and to evaluate the antiviral mechanism of action of PS-ONs. Methods: Various forms of PS-ONs and the control phosphodiester oligonucleotides (PO-ONs) were synthesized and evaluated in infectious HCV cell culture systems. To test the efficacy of PS-ONs in vivo, human hepatocytes transplanted uPA/SCID mice were inoculated with infectious HCV and treated with the PS-ON. Results: The PS-ONs exhibited potent inhibitory activities in both cell culture-generated HCV-JFH1 (HCVcc) and HCV pseudo-particles (HCVpp) systems. This inhibitory activity was size and phosphorothioate dependent but sequence independent. The control PO-ONs had no inhibitory activity against HCV infection. The PS-ONs had no effect on viral replication in the HCV replicon system and binding of HCV-LPs to cells, indicating that the target of inhibition by PS-ONs is at the post-binding, cell-entry step. In human hepatocyte-engrafted uPA/SCID mice, the PO-ONs also appeared to efficiently block de novo HCV infection. Conclusion: The PS-ONs (amphipathic DNA polymers) are promising new class of antiviral compounds that inhibit HCV fusion and entry.

1379 IDENTIFICATION OF MODULATORS OF HCV REPLICATION USING A HIGH-THROUGHPUT SCREEN
Lee F. Peng; GI Unit, Massachusetts General Hospital, Boston, MA
Lee F. Peng, Sun-Suk Kim, Wenyu Lin, Naoya Sakamoto, Nobuyuki Kato, Masanori Ikeda, Stuart Schreiber, Raymond T. Chung Background/Aims: Small organic molecules (SOMs) can exert meaningful biological effects, as evidenced by the fact that the majority of drugs in clinical use today are SOMs, including ribavirin. We have established an efficient, high-throughput automated method to rapidly screen the effects of SOMs on HCV replication. We therefore sought to identify novel SOMs capable of regulating HCV replication. Methods: We optimized the subgenomic pRep-Feo replica Huh7 cell line for the 384-well microplate format, and used this line to previously screen the Bioactives Library (Kim SS et. al., Gastro 2007; 132:311-320). We next used pRep-Feo to screen the DOS Set (a large library of novel diversity-oriented synthesis [DOS] compounds). After identifying several molecules capable of either stimulating or inhibiting HCV replication in this primary screen, we then validated hit compounds using a full-length HCV replicon cell line (OR6) in secondary screens. Results: We identified a number of novel antiviral (41) and pro-viral (20) agents from the DOS Set. Twenty-one of the antiviral compounds came from only two specific libraries of novel epoxide DOS compounds. The antiviral activity of these epoxides was then validated, with the most active compound having an IC50 in the 500 nM range. Using structure-activity relationship analysis, we were able to synthesize a compound with an IC50 approximately 50% of the most potent lead compound of the library from which it was derived. There was no significant cytotoxicity observed at the IC50 for these compounds. Conclusions: We have developed a simple, reproducible, and reliable cell-based high-throughput screening (HTS) assay system using an HCV replicon model to identify novel epoxide compounds that inhibit HCV replication. This method can be used to identify not only putative antiviral agents, but also cellular regulators of viral replication that can be used as probes to study viral biology. Studies to identify cellular targets of these compounds are underway.

1380 DENDRITIC CELLS AND REGULATORY T CELLS AS DECISION MAKERS FOR THE DURATION OF PEGYLATED INTERFERON-α AND RIBAVIRIN THERAPY IN CHRONIC HEPATITIS C PATIENTS
Tatsuya Kanto1, Ichiyo Itose1, Michiyu Inoue1, Naruyasu Kakita1, Masanori Miyazaki2, Hideki Miyatake1, Mitsuru Sakakibara1, Takayuki Yakushijin1, Naoki Hiramatsu1, Tetsuo Takehara1, Akinori Kasahara2, Norio Hayashi1; 1Department of Gastroenterology and Hepatology, Osaka University Graduate School of Medicine, Suita, Japan; 2Department of General Medicine, Osaka University Graduate School of Medicine, Suita, Japan

Backgrounds and aim: The ultimate goal of peg-IFNα and ribavirin therapy in chronic hepatitis C patients is the prevention of hepato-carcinogenesis by eradication of HCV. One of the reasons for treatment failure is high relapse rate after the completion of 48-week treatment. The treatment extension up to 72 weeks may suppress HCV re-appearance in such potential relapsers. Attaining persistently normal ALT levels (biochemical response, BR) is alternatively important, since the long-term incidence of hepatocellular carcinoma is comparably suppressed in BR with those in SVR. According to the 24-week stopping rule, combination therapy may be discontinued in patients who fail to attain negative HCV RNA by week 24. However, some of them become BR if the therapy is continued up to week 48. Thus, the continuation of treatment from 48 to 72 weeks in potential relapsers or 24 to 48 weeks in biochemical responders may give them higher chance of attaining SVR or BR.
respectively. Currently, no reliable marker is available for defining such patients. We thus aimed to evaluate the feasibility of the frequency and function of immune cells, including dendritic cells (DC) and regulatory T cells (Treg), for the predictors of therapeutic outcome. Methods: Twenty-five CHC patients with HCV genotype 1 and high titer were enrolled in this study. They received 48 weeks of PEG-IFNα2b and ribavirin therapy. During the treatment, frequencies of myeloid DC (MDC), plasmacytoid DC (PDC), Treg (CD4+CD25high+) and their changes were determined by means of flow cytometry. The ability of patient DC to stimulate allogenic CD4+ T cells was assessed at the end and after the therapy as reported previously. Results: Among 25 patients who completed the treatment, 11 patients achieved SVR, 11 were transient response (TR) and 3 were non-response (NR), respectively. In comparison among the SVR, TR and NR groups, MDC, PDC and Treg frequencies did not differ throughout the therapy. At week 48 and thereafter, allostimulatory capacity of DC in TR was sustained to be lower than those in SVR patients (p<0.05). By tracing the changes from the beginning to week 24, Treg frequency significantly increased in BR compared to those in non-BR group (p<0.05). Even in patients who failed to clear HCV by week 24, Treg frequency in BR was higher than those in non-BR (p<0.05). Conclusions: In 48 weeks of PEG-IFNα2b and ribavirin therapy, end-of-treatment DC dysfunction and the early phase increase of Treg are served as predictors of relapse and BR, respectively. The extension of treatment needs to be considered in such patients, from the duration based on the rule of early virological response.

1381
DEVELOPMENT OF INTERGENOTYPIC CHIMERIC REPLICONS FOR BROAD-SPECTRUM ANTIVIRAL ACTIVITY DETERMINATION OF HEPATITIS C VIRUS POLYMERASE INHIBITORS
Koleen Herlihy, Joanne Graham, Robert Kumpf, Rohit Duggal, Amy Patrick, Stephanie Shi; Pfizer, San Diego, CA

To address the need for broad-spectrum antiviral activity characterization of HCV polymerase inhibitors, we created a panel of intergenotypic chimeric replicons containing NS5B sequences from genotypes (gt) 2b, 3a, 4a, 5a and 6a HCV isolates. Viral RNA extracted from non-gt 1 HCV patient plasma was subjected to reverse transcription. The NS5B region was amplified by nested PCR and cloned into the corresponding region of the gt 1b (Con-1) subgenomic reporter replicon by SOEing PCR. Stable cell lines were generated with replication competent chimeras for in vitro antiviral activity determination of HCV non-nucleoside polymerase inhibitors (NNPI) that target different regions of the protein. The NNPI1 and NNPI2 binding sites exist in the thumb domain, while the NNPI3 and NNPI4 sites are in the palm domain of the polymerase. Compounds that bind to the NNPI2 and NNPI3 allosteric sites showed 8- to >1280-fold reductions in antiviral activity against non-gt 1 NS5B chimeric replicons compared to the gt 1b replicon. Smaller reductions in susceptibility, ranging from 0.2- to 33-fold, were observed for the inhibitor binding to the NNPI1 site. The inhibitor binding to the NNPI4 site showed broad-spectrum antiviral activity against all chimeric replicons evaluated in this study. Sequence analysis and computer modeling suggest that residues L419 and L482 may facilitate the interactions between gt 1 polymersases and inhibitors targeting the thumb domain. Indeed, introduction of L419 and L482 found in non-gt 1 polymerases into the gt 1b polymerase, either alone or in combination, resulted in varying levels of reduction in susceptibility to inhibitors that bind to the NNPI1 and NNPI2 sites, but no change in susceptibility to interferon and other NNPIs. In conclusion, evaluation of HCV NNPIs against intergenotypic chimeric replicons showed differences in activity spectrum for inhibitors that target different regions of the enzyme, some of which could be associated with specific residues that differ between gt 1 and non-gt 1 polymerases. Our study demonstrates the utility of chimeric replicons for broad-spectrum activity determination of HCV inhibitors.

week. Increased serum 2’,5’-OAS activity and neopterin levels were observed between 4 and 24 hours post administration and both remained above baseline levels for at least 10 days. In conclusion, R7025 demonstrates greatly enhanced in vitro properties ideally suited to the treatment of CHC and a unique ratio of antiviral/immunomodulatory to antiproliferative activity. Further, in vivo, the molecule exhibits PK/PD properties consistent with at least once weekly dosing intervals.

BOTANICAL MEDICINES FOR HEPATITIS C

Stephen J. Polyak1, Jessica Wagoner1, Olivia Kane1, Michael Austin1, David Lee2, Chihiro Morishima1; 1Laboratory Medicine, University of Washington, Seattle, WA; 2Harvard University, Cambridge, MA

Background: A striking feature of hepatitis C virus (HCV) infection is its propensity to establish a chronic disease state. Because state-of-the-art antiviral treatments are costly, have serious side-effect profiles, and moderate probabilities for durable cures, many patients opt for complementary and alternative medicine (CAM)-based approaches to improve liver health. However, mechanisms of action studies are lacking to support the use of CAMs for management of chronic hepatitis C. Methods: In the current study, we examined two widely used botanicals, silymarin and sho-saiko-to (SST), for antiviral and immunomodulatory actions. Results: Silymarin inhibited expression of TNF-α in anti-CD3 stimulated human PBMC and NF-κB dependent transcription in human hepatoma HuH7 cells. Moreover, both silymarin and SST dose-dependently inhibited infection of HuH7 and HuH7.5.1 cells by JFH-1 virus. Both compounds also displayed prophylactic and therapeutic effects against JFH-1 infection, and when combined with IFN-α, inhibited HCV replication more than IFN-α alone. Antiviral effects induced by Silymarin involved Jak-Stat dependent and independent signaling, while SST enhanced ISRE transcription via p38 MAP kinase activation. HPLC fractionation of the herbal preparations permitted identification of the components eliciting antiviral actions. Conclusions: The data demonstrate that standardized silymarin and SST have antiviral action against in vitro HCV infection, and that silymarin has immunomodulatory and anti-inflammatory actions. Therefore, CAM-based approaches may assist in the management patients with chronic hepatitis C.

SVRSCORE: A NOVEL AND HIGHLY PREDICTIVE SCORE FOR SVR PREDICTION IN CHRONIC HEPATITIS C GENOTYPE 1 INFECTED PATIENTS

Philippe Halfon1, Guillaume Pénaranda2, Marc Bourlière3, Albert Tran4, Danièle Botta-Fridlund3, Isabelle Portal4, Christophe Renou5, Magali Picon5, Claire Wartelle5, Jean-Pierre Arpurt6, Michel Anton7, Michel Guisset8, Claude Gueyffier9,11, Patrick Delassalle12, Denis Ouzan13; 1Laboratoire Alphaphia, Marseille, France; 2CDL Pharma, Marseille, France; 3Hôpital Saint-Jospeh, Marseille, France; 4Hôpital l’Arche, Nice, France; 5Hôpital La Conception, Marseille, France; 6Hôpital de Hyères, Hyères, France; 7Hôpital d’Aix en Provence, Aix en Provence, France; 8Centre Hospitalier Henri Duffaut, Avignon, France; 9Cabinet Médical, Orange, France; 10Hôpital Laveran, Marseille, France; 11Centre Hospitalier, Cannes, France; 12Cabinet Médical, Grasse, France; 13Institut Arnault Tzanck, SaintLaurent du Var, France

Background: Previous studies demonstrated that viral load (VL) is an important predictor for treatment outcome in patients with chronic hepatitis C virus (CHC). We looked at pre-treatment (BL) VL and week 4 VL (W4) to assess a predictive score achieving probability of sustained virological response (SVR) in CHC genotype 1 patients: the SVRScore. Patients-Methods: 113 CHC genotype 1 patients were included in the study among which 86 patients achieved complete 48 weeks treatment (54 had an SVR). Patients were treated with PEG IFN alpha 2b+RBV. Serum HCV RNA was measured using COBAS TaqMan HCV Test [TaqMan HCV; Roche Molecular Systems Inc., Branchburg, N.J.]. Binary logistic regression analysis was assessed with BL and W4 VL as predictors of SVR, to obtain the SVRScore. Results: In univariate analysis BL VL and W4 VL were both associated with SVR (<0.001 and p<.01 respectively). In multivariate analysis, BL VL and W4 VL were both independent predictors of SVR (respective odds ratio 0.29 [95% CI 0.09-0.95], and 0.39 [0.24-0.63]. From the binary logistic regression, we calculated the SVRScore combining BL VL and W4 VL (cf. formula below). Area under the ROC curve for SVR prediction was 0.89 and positive predictive value of SVR was 86% (44/51). Conclusions: We developed the SVRScore, a new, simple, and highly predictive score for SVR prediction in CHC genotype 1 infected patients. With high predictive values the SVRScore remain useful for the treatment management of CHC infected patients. A near future analysis will be conducted to validate the SVRScore on an independent cohort.

\[
\text{SVRScore} = \frac{0.6031 - 1.2442(\log_{10} BL\ VL) - 0.9309(\log_{10} W4\ VL)}{1 + 0.6031 - 1.2442(\log_{10} BL\ VL) - 0.9309(\log_{10} W4\ VL)}
\]

The following people have nothing to disclose: Philippe Halfon, Guillaume Pénaranda, Marc Bourlière, Albert Tran, Danièle Botta-Fridlund, Isabelle Portal, Christophe Renou, Magali Picon, Claire Wartelle, Jean-Pierre Arpurt, Michel Antoni, Michel Guisset, Claude Gueyffier, Patrick Delassalle, Denis Ouzan
Background and Aims: Following lead optimization of a novel series of substituted imidazopyridines, GS-9190 was identified as a promising drug candidate based on its potent inhibition of in vitro HCV RNA replication and excellent selectivity index. The aim of this study was to characterize the biological activity of GS-9190 against HCV replicons of different genotypes and against various drug resistant mutants. GS-9190 was also studied in combination with known anti-HCV agents. Methods: The antiviral activity of GS-9190 was evaluated in HCV genotypes 1b, 1a and 2a replicon cells, in the JFH1 (genotype 2a) infectious system, and against several related and unrelated viruses. Cytotoxicity of GS-9190 was determined in a panel of cell lines. A transient replication assay using Lunet cells (Huh-7) was used to characterize susceptibility of known drug resistant mutants to GS-9190. Combinations of GS-9190 with other HCV agents were evaluated in the genotype 1b (Con-1) replicon cells. Results: GS-9190 is a potent inhibitor of HCV genotype 1b and genotype 1a replicon replication (EC50 = 0.6 and 2.5 nM, respectively). The 50% cytostatic concentration of GS-9190 in various cell lines is > 50µM, illustrating a high degree of selectivity (SI > 20,000). GS-9190 has lower potency against a genotype 2a replicon or against the JFH1 infectious virus (EC50 ~ 1 µM) and is inactive against a number of related and unrelated viruses. Replicons resistant to various HCV protease and polymerase inhibitors remained fully susceptible to GS-9190. The combination of GS-9190 with either IFN-α or several HCV protease and polymerase inhibitors resulted in an additive antiviral activity. The combination of GS-9190 with a protease inhibitor was more efficient in clearing hepatoma cells from their replicon than either agent alone. Following long-term culture with increasing concentrations of GS-9190, resistant replicons were selected. Transfection of naïve Lunet cells with total RNA isolated from the GS-9190res replicon cells transferred drug resistance, indicating that resistance is associated with the viral genome. In biochemical assays, GS-9190 is inactive against HCV NS3 serine protease, NS3 RNA helicase, and NS5B polymerase (either in initiation or elongation assays).

A Hepatitis C T-Cell Vaccine Candidate Covering HCV Genotype Complexity and HLA Type Diversity

Annegret Van der Aa1, Vera Goossens1, Koen Allosery1, Gert Verheyden1, Scott Southwood2, Carol Dahlberg2, Denise McKinney2, Mark Newman2, Helmut M. Diepolder3, Geert Maertens3, Marie-Ange Buyse1; 1Innogenetics NV, Zwijnaarde, Belgium; 2Pharmexa-Epimmune Inc., San Diego, CA; 3Immusystems GmbH, München, Germany

Background: Viral clearance of HCV has been shown to be associated with multi-specific, strong CD8+ T-cell (CTL) responses together with strong CD4+ T-cell (HTL) responses. A candidate therapeutic polypeptide T-cell vaccine able to induce such potent specific T-cell responses could ultimately lead to viral clearance. Also, by taking human HLA as well as HCV genotype diversity into account, such a vaccine should be applicable to the majority of infections. Methods: HCV-derived CTL and HTL epitopes for a wide range of HLA class-I and HLA-DRB1 alleles were identified applying different algorithms on the full HCV genome. Further selection was made based on in vitro HLA binding affinity of the peptides, immunogenicity in HLA transgenic mice, and recall reactivity of CD8+ and CD4+ T-cells in an IFNγ-ELISPOT assay using HCV patient samples. Several DNA plasmids containing different sets of selected epitopes were designed, constructed, and evaluated for immunogenicity in HLA transgenic mice. Finally, epitopes were included in the candidate HCV polypeptide therapeutic vaccine based not only on their immunological properties but also their conservancy within and between HCV genotypes, as well as their HLA restriction. In addition, the polypeptide construct was expressed as protein in E. coli, purified using affinity chromatography and tested for immunogenicity. Results and discussion: A plasmid vector was constructed that contains 34 HCV-derived CTL epitopes, 13 HCV-derived HTL epitopes, and the pan-DR helper T-cell epitope PADRE®. Theoretical population coverage calculations show that the selected set of CTL and HTL epitopes can provide recognition of at least four CTL and three HTL epitopes in any HCV genotype 1-infected subject, irrespective of HLA type. Vigorous CTL and HTL responses could be induced using the pDNA or protein formats of the vaccine candidate in HLA-A01, HLA-A02, HLA-A11, and HLA-A24 transgenic mice. Conclusion: A set of HCV-derived CTL and HTL epitopes was identified that showed excellent affinity, immunogenicity, and cross-reactivity, and formed the basis for the development of a universal T-cell vaccine candidate for treatment of chronically infected HCV patients. The T-cell vaccine candidate has now been shown to be immunologically active both in the form of pDNA and protein.

Using Dendritic Cells as Therapeutic or Prophylactic Vaccine Against HCV

Kilian Weigand, Franziska Voigt, Christoph Eisenbach, Birgit Hoyler, Wolfgang Stremmel, Jens Encke; Gastroenterology and Hepatology, University of Heidelberg, Heidelberg, Germany

Dendritic cells (DCs) are a promising tool for therapeutic and/or prophylactic vaccination experiments, considering their multiple functions in immune modulation. We used bone-marrow derived dendritic cells from BALB/c mice loaded with pseudo particles from the hepatitis C virus (HCVpp) to vaccinate naive BALB/c mice. HCVpp consists of the two (genotype 1b) envelope proteins E1 and E2, covering a non-HCV core structure. Thus, not a single epitope, but the whole "viral surface" induces immunogenicity. HCV E1/E2 pseudo particles were successfully established, demonstrated by Huh-7 infection and production of neutralizing antibodies. Then, syngenic BALB/c DCs were ex vivo loaded with HCVpp, after a course of 8 day maturation with GMCS-F and IL-4. This resulted in strong activation of dendritic cells ex vivo, as shown by FACS analyses. For vaccination mature and activated DCs were injected intra peritoneal. To increase immune responses, the BALB/c mice were boosted by the same procedure two weeks after the first immunisation event. Humoral and cellular immune responses were measured by ELISA, ELISPOT and CTL assay. Our results indicate dendritic cells as promising vaccination model to be tested further, for example by surrogate infection experiments.

Efficacy of Interferon β Combined Cyclosporine A Treatment in the Retreatment of Chronic Hepatitis C - Promising Aspect of Host Factor Targeting Therapy

Kazuaki Inoue, Tsunamasa Watanabe, Masaya Yamada, Makoto Yoshiha; Gastroenterology, Showa University Fujigaoka Hospital, Yokohama, Japan

Background/Aim: A significant proportion of chronic hepatitis C patients fails to achieve sustained virological response (SVR) even after the treatment with pegylated interferon (IFN) alpha combined ribavirin. The effective treatment for patients who previously failed combination standard IFN plus ribavirin or pegylated IFN plus ribavirin has not been well established. Management of these patients is the most challenging task and new compounds targeting NS3 protease or NS5B polymerase are now under evaluation. Cyclophilins are essential host factors for HCV replication. We have originally developed IFN combined cyclosporine A treatment and also reported its favorable anti-HCV effect. We report here the efficacy of divided administration of IFNβ plus cyclosporine A in the treatment of chronic hepatitis C patients who failed Peg-IFN or IFN combined ribavirin. Patients and method: We prospectively included 59 patients (median age, 63) with 1) histologically proven chronic hepatitis C, 2) genotype 1b and 3) non-responders and relapsers to combination IFN plus ribavirin or combination pegylated IFN plus ribavirin. We conducted the present study to confirm the efficacy, safety and tolerability of our protocol. Serum HCV RNA level was 3900 KIU/ml. The treatments consisted of an induction therapy, an intensified therapy and a maintenance therapy. The induction therapy comprised intravenous 1 MU IFNβ every 4 hours for the first 3 days, 1.5 MU IFNβ every 6 hours for the next 4 days and 2 MU IFNβ every 8 hours for the following 3 weeks, totaling 168 MU of IFNβ. The intensified therapy was induction therapy shortened to 2 weeks. The maintenance therapy comprised of pegylated IFNα2b and ribavirin. CsA was given 4 times daily for a total dose of 200 mg during the induction and the intensified therapies. Ribavirin was given twice daily for a total dose of 800 mg (body weight over 60 kg) or a total dose of 600 mg (body weight equal to or less than 60 kg) during the maintenance therapy. The institute review board approved this protocol. Results: The end treatment response and sustained virological response rate of the present study were 73% (43/59) and 59% (35/59).

1390 IN VITRO ACTIVITY AND PRECLINICAL PHARMACOKINETICS OF THE HCV PROTEASE INHIBITOR, TMC435350
Kenneth Simmen1, Oliver Lenz1, Tse-l Lin1, Greg Fanning1, Pierre Raboisson1, Herman de Kock1, Gerben van ’t Klooster1, Åsa Rosenquist2, Michael Edlund2, Magnus Nilsson2, Lotta Vrang2, Bertil Samuelsson3; 1Tibotec Pharmaceuticals Ltd., Eastgate Village, Little Island, Cork, Ireland; 2Medivir AB, Box 1086, SE-141 22 Huddinge, Sweden

Background: As a class, HCV NS3/4A protease inhibitors have shown promise in clinical trials for the treatment of chronic hepatitis C virus infection. TMC435350 is a novel and potent macrocyclic NS3/4A protease inhibitor. To further assess the potential of TMC435350, we characterized the in vitro activity of TMC435350 alone or in combination with different classes of HCV inhibitors. The plasma pharmacokinetics and tissue distribution were also studied in vivo. Methods: The effect on HCV RNA level and the emergence of drug-resistant colonies was analyzed in the replicon model with TMC435350 alone, or in combination with interferon alpha, ribavirin, and different HCV polymerase inhibitors. Pharmacokinetic profiles were evaluated following single or repeated dosing in rats. The tissue distribution of TMC435350 was studied in male rats at time points from 0.5 up to 31 hours after a single oral dose of 40 mg/kg. Results: In biochemical HCV NS3/4a protease assays, TMC435350 exhibited Ki values <0.1nM for subtypes 1a (H77) and 1b (conl) enzymes. TMC435350 was found in the subgenomic genotype1b replicon model to have an EC50 of 8nM and a selectivity index [SI] of > 1000. The combination of TMC435350 with different classes of HCV inhibitors further increases its activity in reducing HCV RNA in an additive to synergistic manner, and further reduced the emergence of resistant replicon colonies. After single oral administration of a PEG400-based solution of TMC435350 at 40 mg/kg the mean peak plasma concentration [Cmax] was 1430ng/ml and was observed at two hours post-dose [Tmax]. The absolute bioavailability of TMC435350 was calculated at 44% after single oral administration of a 40 mg/kg dose. TMC435350 was found to be extensively distributed to the liver, small- and large intestines (tissue/plasma ratios >35). Concentrations in other organs were similar to plasma. Notably, TMC435350 was still quantifiable in the liver tissue up to 31 hours post-dosing. Conclusions: TMC435350 is a novel potent and specific HCV protease inhibitor, with good oral bioavailability and a favorable liver distribution. In addition, in vitro studies support the potential use of TMC435350 in combination with other HCV inhibitors.

1391 HCV POLYMERASE (NM107) AND PROTEASE (BOCEPREVIR) INHIBITORS IN COMBINATION SHOW ENHANCED ACTIVITY AND SUPPRESSION OF RESISTANCE IN THE REPLICON SYSTEM
David N. Standring1, Vadim Bichko1, Robert Chase2, Max LaColla2, Lisa Lallos1, Angela Skelton2, Mary Soukasakos2, M. Tausek3, Xiao Tong2, Robert Ralston2; 1Idenix Pharmaceuticals, Cambridge, MA; 2Schering-Plough Research Institute, Kenilworth, NJ

Background: Combination of small-molecule antiviral agents directed against different molecular targets offer an attractive strategy for the effective therapy of hepatitis C. As monotherapies, valopicitabine (NM283) (Idenix/Novartis), an investigational nucleoside NS5B polymerase inhibitor, and boceprevir (SCH 503034) (Schering-Plough), an investigational NS3 protease inhibitor, have demonstrated antiviral activity against hepatitis C virus (HCV) in clinical studies. Using cell culture replicon studies we show that the combination of polymerase and protease inhibitors leads to greater anti-HCV activity, no cross-resistance and the suppression of treatment emergent-resistance, compared to monotherapy with each agent. Methods: The combined antiviral effect of the polymerase and protease inhibitors was evaluated in genotype 1b HCV replicon cells by real time RT-qPCR or ELISA. Possible cross-resistance of these compounds was evaluated using replicon variants carrying single protease inhibitor resistance mutations (T54A, A156S, V170A, A156T), or the polymerase inhibitor resistance mutation (S282T). The selection of resistant cell colonies was carried out for 3-4 weeks in the presence of various concentrations of one or both drugs. Results: The combination of SCH 503034 and NM107 showed dose-dependent enhancement of replicon inhibition, compared with the effect of each inhibitor used alone. No cytotoxicity was observed. In cross-resistance studies, NM107 showed similar antiviral activity (EC50 1.5-2 µM) against wild-type and SCH 503034-resistant replicons. SCH 503034 showed similar activity (EC50 0.3-0.4 µM) against wild-type and NM107-resistant replicons. When tested against their known resistance mutations, each compound showed a 5- to 125-fold loss in susceptibility. In selection experiments, the combination of SCH 503034 and NM107 significantly reduced the frequency of resistant colonies in a dose-dependent manner, compared to each inhibitor used alone. Conclusions: In these in vitro studies, the combination of the polymerase and protease inhibitors showed enhanced anti-replicon activity with no cross-resistance and a greater genetic barrier to resistance. These results support clinical evaluation of this combination in patients with chronic hepatitis C.

ANA598, A NOVEL NON-NUCLEOSIDE INHIBITOR OF HCV NS5B POLYMERASE, EXHIBITS FAVORABLE PHARMACOKINETIC PROPERTIES IN MULTIPLE PRECLINICAL SPECIES

INTRODUCTION: Inadequate responses to current HCV therapy create an urgent unmet need for new antiviral agents to complement today’s standard of care, particularly for treatment of genotype 1 infections. Probable future HCV therapies will add multiple direct-acting antiviral agents taken from differing functional classes to enhance response and suppress the emergence of resistant HCV variants. The essentiality of the NS5B polymerase predicts that inhibitors of this enzyme should be attractive additions to current standard of care. However, first generation development candidates targeting this essential enzyme suffer notable defects in potency, metabolism, or pharmacokinetic properties that limit their potential. We describe here the superior pharmacokinetic properties of ANA598, a novel, orally available and potent “palm site” inhibitor of HCV genotype 1 NS5B polymerase. RESULTS AND DISCUSSION: ANA598 demonstrated high oral bioavailability in all four species evaluated. ANA598 plasma exposures were lower in the rat than the monkey; exposure did not differ significantly for solution and suspension formulations in these species. ANA598 demonstrated a greater than proportional increase in plasma exposures with increasing dose in monkey and rat; in the mouse exposures were approximately dose-proportional up to a 1000mg/kg. An oral dose of 5mg/kg ANA598 to monkeys provided C12 and C24 levels (21,600nM and 7,600nM, respectively) that were substantial multiples of the replicon EC50 (31nM for genotype 1a and 3nM for genotype 1b) even after adjustment for protein binding. ANA598 accumulated in rat liver and reached a liver-to-plasma ratio of ~20 at 12 hours after an oral 5mg/kg dose, suggesting significant additional antiviral coverage in the primary target organ for HCV replication. CONCLUSIONS: Preclinical studies of ANA598 in four species have demonstrated high oral bioavailability and plasma and liver trough levels that are substantial multiples of replicon EC50. The favorable combined characteristics of ANA598 support additional investigation of the compound and clearly differentiate it from other molecules of this functional class.

Plasma PK parameters of ANA598 after a single oral dose of 5mg/kg

ME3738 INHIBITS HEPATITIS C VIRUS REPLICATION BY ENHANCING INTERFERON-β

Yoichi Hiasa1, Yashio Tokumoto1, Ichiro Konishi2, Bunzo Matsusura1, Kojiro Michitaka1, Raymond T. Chung2, Morikazu Onishi1; 1Department of Gastroenterology and Metabolism, Ehime University Graduate School of Medicine, Toon, Japan; 2Gastrointestinal Unit, Massachusetts General Hospital, Boston, MA

Background/Aims: We previously reported that ME3738, a derivative of soyasapogenol B, has effects against hepatitis C virus (HCV) in cells derived from hepatocytes. Our established model of full-length genotype 1a HCV replication supports replication not only in interferon-β (IFN-β) induction-deficient HuH7 cells, but also in HepG2 cells. Therefore, we used our model to examine whether or not ME3738 modifies innate antiviral activity. We also assessed the effects of ME3738 combined with interferon-α (IFN-α) on HCV. Methods: HepG2 or HuH7 cells were transfected with a full-length HCV cDNA plasmid (pH77), and infected with a replication-defective adenoviral vector expressing T7 polymerase (Ad-T7pol). Cells were infected with Ad-T7pol, then ME3738 (0.1-10µM) and/or 100 IU/ml of IFN-α was added. Protein and RNA were harvested from the cells on day 1, 2, 3, 5, 7 and 9 post-infection. To knock down IFN-β expression, 20 nM of siRNA targeting IFN-β was transfected into the cells 1 day before pH77. We measured HCV positive and negative strands as well as mRNA levels of innate antiviral response-related genes using real-time RT PCR.

We assessed HCV core protein expression by ELISA. Results: The anti-HCV effect of ME3738 was more pronounced in HepG2 than in HuH7 cells. ME3738 enhanced mRNA levels of IFN-β in HepG2 cells. The mRNA levels of 2′-5′ oligoadenylate synthetase and MXA were stimulated by IFN-β in HepG2 cells. When the IFN-β was knocked-down by siRNA, the anti-HCV effect of ME3738 was abrogated. In HuH7 cells, the IFN-β mRNA levels triggered by viral double-stranded RNA were increased slightly, and neither IFN-β nor IFN-stimulated gene mRNA expression by ME3738 was enhanced. ME3738 combined with IFN-α elicited synergistic anti-HCV effects in HepG2 cells (HCV/GAPDH copy ratio (Day 3); 2.58±1.60×10^-6 (ME3738+IFN-α) vs. 3.55±1.56×10^-5 (ME3738), p<0.05). Conclusions: The anti-HCV effect of ME3738 was more potent in HepG2 cells than in cells deficient in IFN-β induction. The enhancement of endogenous IFN-β by ME3738 suggests that this agent exerts innate antiviral action more effectively along the type I IFN pathway. Adding IFN-α synergistically enhanced the anti-HCV action of ME3738. Thus, ME3738 might be a useful anti-HCV agent either with or without IFN-α.

PF-00868554, A POTENT NON-NUCLEOSIDE INHIBITOR OF THE HEPATITIS C VIRUS RNA POLYMERASE

Stephanie Shi, Koleen Herlihy, Rebecca Irvine, Susan Binford, Cristina Lewis, Jim Nonomiya, Amy Patrick; Pfizer, San Diego, CA

PF-00868554 is a non-nucleoside inhibitor of the HCV RNA polymerase, which exerts its inhibitory effect by binding to the
thumb-base domain of the protein. It is a potent and selective inhibitor of the enzyme, with a mean IC50 of 0.0096 µM against genotype 1 polymerases in biochemical assays. To determine the in vitro antiviral activity of PF-00868554 against various HCV laboratory and clinical strains, a panel of chimeric replicons was generated in which polymerase sequences derived from genotype 1a and 1b clinical isolates were cloned into the genotype 1b (Con1 strain) subgenomic reporter replicon. The antiviral activity of PF-00868554 was evaluated against this panel of chimeric replicons in the transient replication assay in Huh7.5 cells using the luciferase reporter end-point. Results indicate that PF-00868554 has potent in vitro antiviral activity against a majority (95.8%) of genotype 1a and 1b replicons, with overall mean EC50 and EC90 values of 0.059 and 0.33 µM, respectively. PF-00868554 showed no cytotoxic effect in several human cell lines up to the highest concentration evaluated (320 µM). Furthermore, the antiviral activity of PF-00868554 was retained in the presence of human serum proteins. Our results demonstrate that PF-00868554 has potent and broad-spectrum antiviral activity against genotype 1 HCV strains, supporting its use as an antiviral agent in HCV-infected patients.

1395 MECHANISTIC CHARACTERIZATION OF GS-9190, A NOVEL NON-NUCLEOSIDE INHIBITOR OF HCV NS5B POLYMERASE WITH POTENT ANTIVIRAL ACTIVITY AND A UNIQUE MECHANISM OF ACTION

Hung Shih1, Inge Vliegen2, Betty Peng3, Huiling Yang1, Jan Paeshuyse2, Gerhard Purstinger3, Martijn Fenaux1, Eric Mabery3, Gina Bahador1, Laura S. Lehman1, Steven Bondy1, Winston Tse1, Hans Reiser1, William A. Lee1, Johan Neyts1, Weidong Zhong1, 2Gilead Sciences, Inc., Foster City, CA; 3Rega Institute, Leuven, Belgium; 4University of Innsbruck, Innsbruck, Austria

Background and Aims: GS-9190 is a drug candidate currently being evaluated for safety, tolerability, pharmacokinetics, and antiviral efficacy in chronically infected HCV patients. It is a novel imidazopyridine analogue with potent antiviral activity in HCV replicon cells, especially against genotype 1 HCV. GS-9190 has lower potency against a genotype 2a (JFH1) subgenomic replicon or against the JFH1 infectious virus. The aim of this study was to define the mechanistic action of GS-9190.

Methods: Chimeric replicons carrying sequences from genotype 1b (Cont1-1) and genotype 2a (JFH1) were used to identify viral determinants of susceptibility to GS-9190. A cell-based, strand-specific qRT-PCR replicase assay was employed to analyze the inhibitory profile of GS-9190. Drug resistance selection with GS-9190 was performed in Cont1 replicon cells. Results: To investigate the mechanism of action, we utilized the susceptibility difference between genotype 1b and genotype 2a (JFH1) subgenomic replicon by comparing the viral genome including several inside the beta-hairpin of NS5B. Subsequent studies showed that only those mutations in NS5B were able to confer resistance to GS-9190 when introduced into a wild-type replicon, whereby the total number of mutations correlated with the degree of resistance. Collectively, these data demonstrate that GS-9190 represents a novel non-nucleoside NS5B inhibitor whose binding pocket involves beta-hairpin and is in close proximity to the catalytic active site of NS5B. Detailed mechanistic characterization of GS-9190 and its interaction with NS5B will be presented.

1396 MODELING THE POTENTIAL COST-EFFECTIVENESS OF ADDING A NOVEL STAT-C AGENT TO CURRENT STANDARD THERAPY IN PATIENTS WITH GENOTYPE 1 CHRONIC HEPATITIS C INFECTION

Sumedha P. Galhenage1, Gillian D. Sanders2,3, Keyur Patel1,4, Kevin A. Schulman5,6, John G. McHutchison1,4; 1GI/Hepatology, Duke Clinical Research Institute, Durham, NC; 2Outcomes Research and Assessment Group, Duke Clinical Research Institute, Durham, NC; 3Division of Clinical Pharmacology, Duke University Medical Center, Durham, NC; 4Division of Gastroenterology and Hepatology, Duke University Medical Center, Durham, NC; 5Center for Clinical and Genetic Economics, Duke Clinical Research Institute, Durham, NC; 6Division of General Internal Medicine, Duke University Medical Center, Durham, NC

Background: Current standard of care for chronic hepatitis C (CHC) infection with peginterferon (PEG-IFN) and ribavirin (RBV) (P+R) is costly, and effective in only half of all treated cases. Recent data have shown that the addition of novel Specifically Targeted Antiviral Therapy for HCV (STAT-C) to standard of care has the potential to advance the treatment of genotype 1 CHC infection. Thus, we modeled this new strategy to assess the economic impact of improved viral response on costs and outcomes. Methods: A Markov model was developed to compare standard therapy with 4 treatment strategies (a STAT-C agent for 12 weeks combined with P +/− R for 12-48 weeks). The model followed treatment-naïve individuals with mild CHC infection (Metavir FO-F1) from treatment initiation until death. Costs of PEG-IFN α-2a 180mcg weekly and RBV 1000-1200mg daily were based on average wholesale prices. Base cost of STAT-C therapy was assumed equivalent to 48 weeks of P + R. Rates of SVR and adverse effects were estimated. Natural history of CHC infection, treatment patterns, healthcare costs and utilities for all disease states were obtained from published data. AM3 INHIBITS HCV REPLICATION THROUGH ACTIVA-
TION OF PERIPHERAL BLOOD MONONUCLEAR CELLS

Pedro L. Majano 2, Samuel Martín-Vílchez 1, Yolanda Rodríguez-
Munoz 1, Paloma Sanz Cameno 1, Francisca Molina-Jimenez 2, Jose L. Alonso 4, Salvador Gonzalez 2, Manuel Lopez-Cabrera 2, Ricardo Moreno-Otero 4, Paloma Sanz Cameno 1, Francisca Molina-Jimenez 2, Salvador Gonzalez 2, Manuel Lopez-Cabrera 2, Ricardo Moreno-Otero 4

INTRODUCTION Immunoferon® is a drug whose active princi-
ple is a glycoconjugate of natural origin composed of a glu-
cosyranosyl polysaccharide from Candida utilis and a storage
protein from nongerminated seeds of Ricinus communis. The
glycoconjugate that constitutes the active principle of
Immunoferon® (hereafter referred as AM3) has been shown to
modulate regulatory and effector functions of the immune sys-
tem by acting on peripheral blood mononuclear cells (PBMCs)
and modifying the expression of extracellular mediators, such
as tumor necrosis factor alpha (TNF-α) and interleukin-1 beta.
Previously, it has been shown that AM3 has antiviral effect
against HBV due to stimulation of secretion of molecules with
antiviral properties by PBMC. OBJECTIVE: To analyze whether
AM3 has antiviral properties against HCV replication in vitro.
MATERIALS AND METHODS: Reagents: AM3 was prepared
according to the methods described in patents P9900408 (Spain)
and PCT/ES99/00338. The phosphorylated glu-
cosylmannon polysaccharide and the protein were combined in a
5:1 (wt/wt) polysaccharide/protein proportion. Cell culture: We
used two clones derived from Huh-7 cell with genomic bicistronic,
full-length HCV genome. PBMCs were purified from peripheral
blood cells from healthy donors by Ficoll density
centrifugation and cultured at 106 cells/ml for 24 h prior to
analysis. PBMC were stimulated or not with AM3 (1 µg/ml) for
48 or 96 h and then cell supernatants were collected. Huh7/HCV clones were treated for 24 or 48 h with the PBMC
supernatant (conditioned medium; 1:2 proportion, with normal
culture medium). To analyse whether AM3 has a direct antiviral
effect on HCV replication, Huh7/HCV clones were incubated
with various doses of AM3 for 48 h. Methods: Total RNA
Huh/HCV clones were isolated and HCV RNA was analyzed
by real-time RT-PCR. Additionally, core and non-structural pro-
tein NS5a levels were determined by western blot. RESULTS:
HCV replicons cells treated with supernatant derived from AM3
stimulated PBMC exhibit lower HCV RNA and protein accumu-
lation when compared to untreated controls. However, AM3
did not affect directly the expression of RNA or protein in any
of the cell clones tested. CONCLUSION: In this report, we
found that AM3 inhibited HCV RNA and protein expression by
an indirect mechanism. We found that AM3 lacked intrinsic
antiviral properties, and that the antiviral effect of the glyco-
conjugate was due to stimulation of secretion of molecules with
antiviral properties by PBMC. Our data suggest that the
employment of AM3 as an adjuvant administered simultane-
ously with conventional antiviral drugs may potentiate the
endogenous response against viral infection.

1398
PRECLINICAL PHARMACOKINETIC CHARACTERIZATION OF GS-9190, A NOVEL NON-NUCLEOSIDE HCV NS5B
POLYMERASE INHIBITOR

Chris Yang, Yujin Wang, Lani Wieman, Eugene Eisenberg, Melody
Lee, Bernard Murray, Leah Tong, Adrian Ray, Steven Bondy, Winston
Tse, Amy Coluci, Matthew Wright, Laura S. Lehman, William A. Lee, Gerald Rhodes; Gilead Sciences, Foster City, CA

Background and Aims: GS-9190 is a novel non-nucleoside HCV RNA polymerase inhibitor with potent in-vitro antiviral
activity and a high selectivity index. GS-9190 is currently being
evaluated for safety/tolerability, pharmacokinetics and antiviral
efficacy in chronically infected HCV patients. It is a novel imi-
dazopyridine analogue with potent antiviral activity against
 genotype 1 HCV replicon cells. The aim of these studies was to
characterize the pharmacokinetic profile of GS-9190 in rele-
vant preclinical models prior to administration in humans. Meth-
ods: Single dose pharmacokinetic studies were conducted
following intravenous and oral administration of GS-9190 in
rats, dogs and cynomolgus monkeys. The distribution and
routes of excretion were determined in rats following oral
administration of 14C-GS-9190. The absorption, metabolic sta-
bility, protein binding and the CYP450 inhibition and induction
profile of GS-9190 were evaluated in vitro in systems derived
from human and, where appropriate, preclinical species. Results:
GS-9190 was stable to in vitro metabolism in microso-
lates, dogs and cynomolgus monkeys. The distribution and
clearance and a volume of distribution comparable to
body water. Oral bioavailability was greater than 30 % in

1397
AM3 INHIBITS HCV REPLICA
all preclinical species and was not limited by hepatic first pass extraction. In the rat, the majority of the 14C-radiolabelled dose was excreted slowly into the bile with only minor excretion in the urine. Recovery of radioactivity was essentially complete 48 hr after administration of 14C-GS-9190. The available human in vitro data project a favorable clinical pharmacokinetic profile, with high oral bioavailability for GS-9190 in human subjects. As a result it is predicted that plasma concentrations of GS-9190 sufficient to drive pharmacological effect can be achieved with relatively modest doses in humans.

**Background:** Tenofovir Disoproxil (TDF) is a nucleotide analogue approved for the treatment of HIV-1 with activity against hepatitis B virus (HBV). The primary objective of this Phase III, 5 year study was to compare the safety and efficacy of 300 mg TDF versus 10 mg ADV at 48 weeks in subjects with HBsAg + CHB. **Methods:** This was a double-blind, active-controlled, study of mono-infected subjects with HBsAg+ CHB who were randomized in a 2:1 ratio to TDF:ADV. Entry criteria included subjects 18-69 years of age with compensated liver disease, ALT>2xULN, HBV DNA>10^6 copies/mL and a Knodell necroinflammatory score without worsening in the midzone accompanied by accentuated elevation of plasma ALT levels as compared to alcohol-fed wt mice (95% 18-21). This pathology resembled necrosis commonly frequent in the TDF group (19%) vs ADV group (10%). Renal safety was excellent; no TDF subject had a confirmed 0.5 mg/dL creatinine increase or creatinine clearance <50 mL. TDF was well tolerated with no TDF subject discontinuing due to an AE and with the majority completing primary endpoint assessments (90%TDF,93%ADV). Primary and secondary efficacy endpoints are summarized below. **Conclusion:** TDF, at a dose of 300 mg QD, was well tolerated and demonstrated superior efficacy to ADV through 48 weeks as illustrated by the higher percentage of HBeAg+ subjects achieving the primary efficacy endpoint and most secondary endpoints.

ACTIVATION OF TLR4-TRA6-FK1 PATHWAY INDUCES HEPATOCELULAR CARCINOMAS BY SYNERGISTIC INTERACTIONS BETWEEN ALCOHOL AND HEPATITIS C VIRUS NSSA

Keigo Machida1, Hidekazu Tsukamoto2, Hasnik Mkrtchyan2, Alla Dynyk2, Helene Liu3, Jiaohong Wang3, Ranjit Ray3, Ratna Ray4, Michael M. Lai1; 1Molecular Microbiology and Immunology, University of Southern California Keck School of Medicine, Los Angeles, CA; 2Pathology, University of Southern California Keck School of Medicine, Los Angeles, CA; 3Internal Medicine, St. Louis University, St. Louis, MO; 4Pathology, St. Louis University, St. Louis, MO

**Background:** Alcohol exacerbates hepatitis C virus (HCV)-induced liver disease as exemplified by their synergistic effects on the incidence of hepatocellular carcinoma (HCC). Inflammation plays an important role in HCC oncogenesis. HCV NSSA protein induces expression of TLR4, which mediates inflammation in response to endotoxin. It is yet to be tested whether TLR4 induction plays a role in the alcohol-HCV synergism for oncogenic potential. **Objectives** We aimed to determine whether chronic alcohol intake causes synergistic induction of HCC by HCV NSSA in mice. **Methods** HCV NSSA transgenic (Tg) and wild type (wt) mice were fed with Lieber-DeCarlie alcohol diet for 12 months or infused with alcohol diet for 4 week by intragastric infusion model. **Results** HCCs in NSSA Tg mice were induced by 12-month-chronic alcohol feeding (0% vs. 25%). Further, 4-week-ethanol-infused NSSA Tg mice displayed sub-massive necrosis and inflammation in the midzone accompanied by accentuated elevation of plasma ALT levels as compared to alcohol-fed wt mice (95%±18 vs. 181±21). This pathology resembled necrosis commonly observed in chronically ethanol-fed rodents given acute lipopolysaccharide (LPS) and is consistent with TLR4-mediated injury in NSSA Tg mice. Further, weekly enteral administration
of LPS to ethanol-fed NS5A Tg mice resulted in an additional increment in ALT levels and pathology. LPS injection in NS5A Tg mice increased mortality, liver damage, and TNF-α production through TGF-β-activated kinase 1 (TAK1) and TNFR-associated factor 6 (TRAF6) complexes and phosphorylation of JNK in liver. TAK1-TRAF6 complex formation was induced in HCCs in NS5A Tg mice fed with alcohol. These results demonstrate that alcohol feeding induces HCCs in the liver of NS5A Tg mice through induction of TLR4. The TLR4 signaling molecules, involving TAK1, TRAF6, and JNK, are involved in alcohol-induced oncogenesis in NS5A Tg mice. We conclude that there is a synergistic interaction between HCV proteins and alcohol because of the enhanced endotoxin-induced inflammation through TLR4.

EVALUATION OF VIRAL VARIANTS DURING A PHASE 2 STUDY (PROVE2) OF TELAPREVIR WITH PEGINTERFERON ALFA-2A AND RIBAVIRIN IN TREATMENT-NAIVE HCV GENOTYPE 1-INFECTED PATIENTS
Taral Kiefer1, Yi Zhou1, Eileen Zhang1, Michelle Marcial1, Randal Byrn1, Thomas Pfeiffer1, Janice Miller1, Ann Tigges1, Doug Bartels1, Ann Kwong1, Peter Ferenci2, Geoffrey Dusheiko2, Stefan Zeuzem3, Jean-Michel Pawlotsky4, Infectious Diseases, Vertex Pharmaceuticals Incorporated, Cambridge, MA; 2Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; 3Centre for Hepatology, Royal Free Hospital, London, United Kingdom; 4Department of Medicine I, J.W. Goethe University Hospital, Frankfurt, Germany; 5Department of Virology, Henri Mondor Hospital, University of Paris XII, Créteil, France

Background: The VX05-950-104EU study (PROVE2) is a Phase 2 study of an HCV protease inhibitor, telaprevir (VX-950, TVR) 750 mg q8h, in combination with Peg-IFN-alfa-2a (P) 180 µg/week and ribavirin (R) 1000-1200 mg/day in treatment-naive subjects with genotype 1 hepatitis C. Subjects were randomized into 4 groups that received: 1) TVR/P/R for 12 weeks, 2) TVR/P for 12 weeks, 3) TVR/P/R for 12 weeks followed by 12 weeks of P/R, and 4) P/R for 48 weeks (control group). Viral breakthrough (increase of > 1-log above HCV RNA nadir or increase to > 100 IU/mL in previously undetectable patients) was observed in some subjects during the first 12 weeks of therapy. Viral sequencing was used to evaluate the contribution of TVR resistance to antiviral response. Methods: Plasma samples for viral sequencing were taken at baseline and at each HCV RNA assessment. The NS3-4A RNA region was amplified by nested RT-PCR and sequenced in samples with HCV RNA > 1,000 IU/mL. Prospectively defined criteria for identifying potential resistance mutations were applied using a Poisson distribution. Results: HCV RNA was undetectable (LOD 10 IU/mL) for viral sequencing were taken at baseline and at each HCV RNA assessment. The NS3-4A RNA region was amplified by nested RT-PCR and sequenced in samples with HCV RNA > 1,000 IU/mL. Prospectively defined criteria for identifying potential resistance mutations were applied using a Poisson distribution. Results: HCV RNA was undetectable (LOD 10 IU/mL) at Week 4 in 14% of subjects in the P/R group, 74% in the TVR/P/R groups (p<0.001), and 53% in the TVR/P group (p<0.001); and at Week 12 in 43% of subjects in the P/R group, 79% in the TVR/P/R groups (p<0.001), and 63% in the TVR/P group (p<0.015). During the first 12 weeks on treatment, 6 of 152 subjects (4%) in the TVR/P/R groups, 19 of 76 subjects in the TVR/P group (25%), and 1 of 77 subjects (1%) in the P/R group had viral breakthrough. The breakthroughs were associated with wild-type virus in the P/R group and previously identified TVR-resistant variants in the TVR groups TVR/P/R: genotype 1a, n=4: mainly V36M and R155K; genotype 1b, n=2: mainly A156T; TVR/P: genotype 1a, n=12: mainly V36M and R155K; genotype 1b, n=7: mainly V36A, T54A, R155K, and A156S/T). Conclusions: In this interim analysis, TVR/P/R produced a significantly greater antiviral response at Weeks 4 and 12 compared to TVR/P and P/R in treatment naive subjects with genotype 1 HCV. In the TVR groups, viral breakthroughs were associated with the selection of known TVR-resistant variants. The breakthrough rate in the TVR/P group was higher than in the TVR/P/R groups, suggesting that suboptimal inhibition of viral replication provides a greater probability for selection of TVR-resistant variants. Some subjects with viral breakthrough on TVR had a subsequent decline in HCV RNA during treatment with P/R, indicating that emergence of TVR-resistance does not preclude response to P/R. *on behalf of the PROVE2 Study Team

LB9
ANTIVIRAL ACTIVITY, PHARMACOKINETICS, SAFETY, AND TOLERABILITY OF R7128, A NOVEL NUCLEOSIDE HCV RNA POLYMERASE INHIBITOR, FOLLOWING MULTIPLE, ASCENDING, ORAL DOSES IN PATIENTS WITH HCV GENOTYPE 1 INFECTION WHO HAVE FAILED PRIOR INTERFERON THERAPY
Rajender Reddy1, Maribel Rodriguez-Torres2, Ed Gane3, Richard Robson4, Jacob Lalezari5, Gregory T. EVerson6, Edwin DeJesu5, John G. McHutchison8, Hugo E. Vargas8, Amanda Bead9, Carlos A. Rodriguez11, George Z. Hill11, William Symonds10, Michelle Berrey10,12, University of Pennsylvania, Philadelphia, PA; 2Fundacion de Investigacion de Diego, Santurce, PR; 3Auckland Clinical Studies Limited, Auckland, New Zealand; 4CCST, Christchurch, New Zealand; 5Quest Clinical Research, San Francisco, CA; 6University of Colorado, Aurora, CO; 7Orlando Immunology Center, Orlando, FL; 8Duke Clinical Research Institute, Durham, NC; 9Mayo Clinic, Phoenix, AZ; 10Pharmasset, Inc., Durham, NC; 11Roche, Palo Alto, CA

Background: R7128 is a prodrug of PSI-6130, an oral cytidine nucleoside analog polymerase inhibitor, currently in development for the treatment of HCV. This multiple ascending dose study assessed safety, tolerability, pharmacokinetics, and preliminary antiviral activity of R7128 in subjects with HCV genotype 1 infection. Methods: Multiple oral doses of R7128 monotherapy were administered for 14 days to 40 HCV-infected patients (n=10 per cohort with 8 active + 2 placebo) of 750mg QD, 1500mg QD, 750mg BID & 1500mg BID. PK, safety and virology assessments were conducted throughout the study period. Data are available for the 750mg QD, 1500mg QD and 750mg BID cohorts. The 1500mg BID cohort is fully...
enrolled. **Results:** All subjects had HCV genotype 1 (29 – 1a; 11 – 1b), had previously failed alpha-interferon and were non-cirrhotic. There were no SAEs reported and no AEs required dose modification; no clinically significant changes in vital signs, ECGs, hematology, renal or other laboratory parameters occurred. Preliminary data on adverse events (AEs) reported during treatment in subjects receiving R7128 include a total of 32 events in 14 of 24 subjects, most of mild intensity as compared to 26 events in 5 subjects receiving placebo. 18 AEs were reported in 7 subjects that received 750mg QD, 3 AEs in 3 subjects receiving 1500mg QD, and 11 AEs in 4 subjects receiving 750mg BID. The most frequently reported AEs for patients receiving R7128 were headache (8), dry mouth (2), nausea, (2) and upper respiratory infection (2); in subjects on placebo, headache (3) and diarrhea (3) were most commonly reported. The baseline HCV RNA concentrations, ranging from 5.2 to 7.4 (log10 IU/mL), and mean change from baseline observed, ranging from -0.7 to -2.9 (log10 IU/mL) for active, are summarized in the table below. Plasma exposure to the prodrug, R7128, was negligible; exposure to PSI-6130 and a uridine metabolite, PSI-6206, increased with increasing doses of R7128. Terminal half-life was approximately 5 h for PSI-6206, increased with increasing doses of R7128. Terminal half-life was approximately 5 h for PSI-6130 and 20 h for psi-6206. **Conclusion:** R7128 monotherapy was generally well-tolerated and resulted in significant, dose-dependent suppression of HCV replication following 14 days of monotherapy. These results support continued development of R7128 for the treatment of HCV infection in combination with pegylated interferon and ribavirin. Results for the 1500 BID cohort will be available for presentation.

**PHASE 2A STUDY TO EVALUATE THE SAFETY AND TOLERABILITY AND ANTI-VIRAL OF 4 DOSES OF LOCTERON**

Iryna Dzyublyk1, Tetiana Yegorova2, Larisa Moroz3, Oleksandra Popovych3, Igor Zaytsev4, Vladimir Miroshnichenko5, Eva Herrmann5, Stefan Zeuzem6, Ewoud J. van Hoogdalem7, John E. Humphries8; 1PL Shupyk National Medical Academy of Postgraduate Education, Kyiv, Ukraine; 2Kiev City Hospital, Kiev, Ukraine; 3M.I. Pyrogov Vinnitsa National Medical University, Vinnitsa, Ukraine; 4M. Gorky Donetsk State Medical University, Donetsk, Ukraine; 5Saarland University Hospital, Homburg/Saar, Germany; 6Saarland University, Homburg/Saar, Germany; 7Octoplus, N.V., Leiden, Netherlands; 8Biolet Therapeutics, Pittsboro, NC

Background: Controlled-release recombinant interferon-alfa 2b (Locteron) is a novel approach to delivery of interferon (IFN) given every 2 weeks with improved tolerability combined with a high level of hepatitis C virus (HCV)RNA reduction. Methods: A phase 2a, open-label, dose-ranging study was conducted in treatment-naive patients with genotype 1 chronic HCV infection to evaluate the safety, tolerability and anti-viral effect of Locteron. 32 patients were randomized to receive subcutaneous injections of Locteron 14 days apart over 12 weeks in 4 dose cohorts (8 per cohort) of 160, 320, 480 and 640 µg, with the 640 µg group starting after safety evaluation of the other cohorts. All subjects received weight-based ribavirin. HCV RNA reduction modeling was performed. Results: The mean HCV RNA reduction at week 4 for the 160, 320, 480 and 640 µg groups were 1.1, 3.1, 2.9 and 3.1 logs, respectively. Percent of HCV negative subjects at week 4 were 0, 25, 38 and 25, respectively. Average viral reduction after 12 weeks for the 3 lower doses of Locteron (160, 320 and 480 µg) was 1.8, 4.5 and 4.2 logs, respectively. 63% of subjects at the 2 middle doses (320 & 480 µg) were HCV negative (LLOQ < 28 IU/mL) at 12 weeks. Early viral response (EVR: 12-week ≥ 2-log drop in HCV RNA) was achieved in 88% and 100% of subjects in the 320 and 480 µg Locteron dose cohorts, respectively. Modeling of HCV kinetics demonstrated dose-dependent biphasic kinetics reflected by mean and maximum efficiency in blocking viral production from day 1 to day 28 of treatment. Mean and maximum efficiency were 41%±23% and 54%±27%, respectively, in the 160 µg cohort, 58%±19% and 71%±21% in the 320 µg cohort, 72%±20% and 84%±11% in the 480 µg cohort, and 73%±24% and 80%±22% in the 640 µg cohort. The median T1/2 of free HCV RNA was 2 weeks and the median T1/2 of infected cells was 2.8 days. Clinical adverse events were almost exclusively mild in intensity with only 1 severe adverse event in the 3 lower dose cohorts. The most common adverse events were arthralgia (50%), weakness (50%), myalgia (38%) and headache (33%), with chills, nausea and diarrhea each reported in fewer than 5% of subjects. Fever (Temp ≥ 38.0°C) occurred in only 1 subject in these first 3 cohorts. Full data on all 4 cohorts for all 12 weeks will be available by the AASLD meeting. Conclusions: In this study, Locteron, a controlled-release formulation of unmodified IFN-alfa 2b, administered every 2 weeks to treatment-naive patients with chronic hepatitis C (genotype 1) demonstrated strong anti-viral activity combined with an improved safety and tolerability profile compared to currently marketed IFNs and those in development.

Antiviral activity of the non-nucleoside polymerase inhibitor, VCH-759, in chronic hepatitis C patients: results from a randomized, double-blind, placebo-controlled, ascending multiple-dose study.

Curtis Cooper1, Eric J. Lawitz2, Peter Ghali3, Maribel Rodriguez-Torres4, Frank H. Anderson5, Samuel S. Lee6, Louise Proulx7
1Department of Internal Medicine, Division of Infectious Disease, The Ottawa Hospital, Ottawa, ON, Canada; 2Alamo Medical Research, San Antonio, TX; 3Department of Gastroenterology and Hepatology, McGill University Health Center, Royal Victoria Hospital, Montréal, QC, Canada; 4Fundación de Investigación de Diego San Juan, PR; 5Liver and Intestinal Research Center, Vancouver, BC, Canada; 6Liver Unit, University of Calgary, Calgary, AB, Canada; 7ViroChem Pharma Inc, Laval, QC, Canada

Background: VCH-759 is a novel, orally bioavailable non-nucleoside inhibitor of hepatitis C virus RNA-dependent RNA polymerase. It has demonstrated sub-micromolar IC50 against the HCV replicons of genotype 1a and 1b. Methods: This multiple ascending dose study was designed to assess the effect on viral kinetics, viral resistance, pharmacokinetics, safety and tolerability of VCH-759 given as monotherapy for 10 days with a 14-day follow-up period. Three cohorts of treatment-naive chronic hepatitis C patients infected with HCV genotype 1 received either placebo, 400 mg tid, 800 mg tid or 800 mg bid. Viral loads were determined using the Roche Amplicor assay (lower limit of quantification=600 IU/ml). VCH-759 plasma levels were assessed over 6 hours for the tid regimen and over 12 hours for the bid regimen on Days 1 and 10 and daily, prior to the morning dose, on Days 1 to 11. Results: Thirty-two (32) subjects were enrolled and completed the study: 9: placebo, 9: 400mg tid, 9: 800 mg tid, 5: 800 mg bid. VCH-759 was rapidly absorbed with peak plasma levels of 1857 ± 773 ng/ml, 3675 ± 2213 ng/ml and 4627 ± 94 ng/ml at Day 1 for the 400 mg tid, 800 mg tid and 800 mg bid doses respectively. All subjects had more than a one log reduction with values ranging between 1.4 and 2.6 log10 for the 400 mg tid dose, 1.5 and 2.9 log10 for the 800 mg bid dose and 1.2 and 3.3 log10 for the 800 mg tid dose. The mean maximal decrease in HCV RNA log10 was 1.9, 2.3 and 2.5 for the 400 mg tid, 800 mg bid and 800 mg tid doses respectively. The plasma levels at trough (before the morning dose) were higher than the IC90 (420 ng/ml) between Days 2 and 11 for 800 mg tid and between Days 2 and 7 for 800 mg bid. VCH-759 was well tolerated with the most frequent adverse events being gastrointestinal disorders (most likely due to the formulation vehicle used) reported in both the active and the placebo groups. Conclusions: VCH-759 achieved a 2 log10 or larger decline in HCV RNA at doses of 800 mg tid and bid. VCH-759 was well tolerated with no serious adverse events and no discontinuation. Genetic sequencing of NS5B is ongoing. Further studies combining VCH-759 with current therapies are warranted.

Restoration of the defective innate immune system following treatment with the probiotic Lactobacillus casei Shirota in patients with alcoholic cirrhosis: a proof of concept study

Vanessa Stadlbauer, Rajeshwar P. Mockereeje, Stephen Hodges, Gavin A. Wright, Nathan Davies, Rajiv Jalan; The Institute of Hepatology, University College London, London, United Kingdom

Introduction: Our recent studies showed that in patients with alcoholic cirrhosis, neutrophil phagocytic dysfunction is associated with increased incidence of infection and mortality, and this dysfunction is possibly mediated by endotoxaemia. As probiotics are known to alter gut flora and decrease gram-negative organisms, we hypothesized that probiotic treatment in patients with alcoholic liver disease restores neutrophil function. Methods: In an open-label study, twelve patients with alcoholic cirrhosis received food supplementation with Lactobacillus casei Shirota (6.5×109) 3 times a day for 4 weeks. Neutrophil oxidative burst, phagocytosis, toll-like receptor (TLR) expression, plasma cytokines and cytokine production after ex vivo stimulation were measured. Data are given as mean±SEM in table 1. Results: Baseline neutrophil phagocytic capacity was significantly lower in patients compared with controls (73% versus 98%, p<0.05), which normalized after a 4 week treatment with probiotics (73% increasing to 100%, p<0.05). Stimulated lev-
els of TNFR1, TNFR2 and IL-10 significantly decreased following treatment (42%, 43% and 34% respectively, p<0.05). TLR2 (p<0.05), TLR4 (p<0.01) and TLR9 (p<0.05) expression were significantly higher in patients than in controls. Probiotic therapy resulted in significant reduction in TLR4 (p<0.05) surface expression compared to baseline. During treatment with the probiotic no adverse events were noted; compliance to the study medication was 86%. In conclusion, we make the novel observation of marked neutrophil functional defect in well-compensated alcoholic cirrhosis and a predominant anti-inflammatory cytokine production ex vivo which may make the patients with alcoholic cirrhosis more susceptible to infection. Treatment with Lactobacillus casei Shirota for four weeks is safe and, normalises the phagocytic capacity and cytokine response to lipopolysaccharide. Our data suggests an important mechanistic role for TLR 4 in the mediation of the neutrophil functional defect, and establish a proof-of-concept that probiotics restore innate immune function in cirrhosis, warranting further randomized, well powered, controlled studies.

** LB14 FIRST EVIDENCE THAT ALBUMIN CAN DIRECTLY IMPROVE CARDIAC CONTRACTILITY IN CIRRHOTIC RATS**

Giulio Ceolotto, Italia Papparella, Maurizio Cavalli, Antonietta Sticca, Lorenzo Franco, Sergio Bova, Andrea Semplicini, Angelo Gatta, Paolo Angeli; Dept Clinical and Exp medicine, University of Padova, Padova, Italy

A low cardiac output due to cirrhotic cardiomyopathy could be a critical factor in the pathogenesis of hepatorenal syndrome (HRS) in cirrhosis. Albumin together with vasoconstrictor drugs is widely used in the management of HRS however the mechanisms are still unclear. Aim of our study was to verify whether albumin infusion may restore a normal cardiac contractile response to β-adrenergic agonists and to improve β-adrenergic signal transduction in an animal model of cirrhosis with ascites. 12 Wistar Kyoto rats were treated for 15 weeks by inhalation with carbon tetrachloride (CCl4) to induce cirrhosis and 12 rats were used as control animals. Three days and one day before the sacrifice, albumin was administered as saline solution at a dose of 3g/kg B.W. i.v. to 8 cirrhotic and to 8 control rats. In 4 cirrhotic rats the same amount of saline solution was administered at the same times. Left ventricular contractility was determined in isolated hearts with a β-agonist, isoproterenol. Cardiac gene expression of β-adrenergic signalling was performed by Real-Time PCR. Plasma antioxidant capacity was evaluated with Electron Spin Resonance spectroscopy. The maximal response of cardiac contractility induced by isoproterenol (10-8 mol and 10-6 mol) was significantly reduced in the left ventricular tissue of cirrhotic rats in comparison to controls (p<0.01). In albumin-treated cirrhotic rats, isoproterenol-induced cardiac contractility was stronger in comparison to saline-treated cirrhotic rats (p<0.01) and it was not significant
different than controls. In hearts from saline-treated cirrhotic rats, gene expression analysis showed a significant overexpression of G protein alpha inhibiting subunit 2 (Gai2) (p<0.01), of regulator of G-protein signalling (RGS2) (p<0.01) and of phosphodiesterase-2a (PDE), as compared to control rats. In albumin-treated cirrhotic rats, gene expression of RGS2 and PDE2a was lower in comparison to saline-treated cirrhotic rats alone (p<0.01) and was similar to control animals. No difference was observed for Gai2 expression between saline-treated and albumin-treated cirrhotic rats. Plasma antioxidant capacity was decreased in cirrhotic rats compared to the control rats (to 57% ± 8%, p<0.01). The administration of albumin almost completely restored the antioxidant level in cirrhotic rats. These results demonstrate for the first time that the administration of albumin improve cardiac contractility and β adrenergic signal transduction by modulating the expression of RGS2 and PDE2a in cirrhotic rats. All these effects were accompanied by an increase of the level of antioxidant status in these animals.

**LB15 EFFICACY AND SAFETY OF VALOPICITABINE IN COMBINATION WITH PEGYLATED INTERFERON-α (PEG IFN) AND RIBAVIRIN (RBV) IN PATIENTS WITH CHRONIC HEPATITIS C**

Fred Poordad¹, Eric J. Lawitz², Norman Gitlin³, Maribel Rodriguez-Torres⁴, Terry Box⁵, Tuan Nguyen⁶, Keith Pietropaolo⁷, Wei Liu², Barbara A. Fielman¹, Douglas Mayers⁵, ¹Cedar-Sinai Medical Center, Los Angeles, CA, ²Alamo Medical Research, San Antonio, TX, ³Atlanta Gastroenterology Associates/Emory University, Atlanta, GA, ⁴Fundacion de Investigacion de Diego, Santurce, PR, ⁵Mountain West Gastroenterology, Salt Lake City, UT, ⁶Tuan Nguyen, MD, San Diego, CA, ⁷Idenix Pharmaceuticals, Cambridge, MA

Background: Future HCV therapy will likely combine drugs with different modes of action and complementary resistance profiles. We investigated the pharmacokinetics, antiviral activity and safety of valopicitabine, an investigational NS5B polymerase inhibitor, combined with PegIFN and RBV. Methods: 117 treatment-naïve HCV genotype 1 patients with compensated liver disease were randomized among 3 arms: (1) valopicitabine 200 mg QD + PegIFNα2a 180 µg QW, (2) RBV 1000-1200 mg daily + valopicitabine 200 mg QD + PegIFNα2a 180 µg QW, or (3) RBV 1000-1200 mg daily + valopicitabine placebo QD + PegIFNα2a 180 µg QW. Patients received valopicitabine (or placebo) for 1 week prior to PegIFN with or without weight-based RBV on Day 8, and continued treatment for 12 weeks. After Week 12, patients received 36 weeks of PegIFN/RBV. Results: There was no PK drug-drug interaction detected between valopicitabine and RBV. As-treated analysis demonstrated a mean HCV RNA difference between the triple combination group and PegIFN /RBV of 0.45-0.66 log10 IU/mL; this was maintained at each study visit. HCV RNA PCR-negativity rates at Weeks 4, 8 and 12 were also greater in the triple combination group (16%, 56%, 72%, respectively) vs PegIFN/RBV (5%, 37%, 62%) and PegIFN/valopicitabine (11%, 33%, 44%). By ITT analysis, HCV RNA PCR-negativity rates at Week 12 were 67%, 62% and 44% for PegIFN/RBV/valopicitabine, PegIFN/RBV, and PegIFN/valopicitabine, respectively. Three patients, all recipients of valopicitabine triple combination therapy, discontinued prematurely, one for vomiting attributed to valopicitabine. One serious adverse event was reported in a PegIFN/RBV/valopicitabine recipient and attributed to PegIFN. Through Day 36, GI-related adverse events were reported in 77% of PegIFN/RBV/valopicitabine recipients and 67% of PegIFN/valopicitabine recipients, vs 49% of the PegIFN/RBV group that did not receive valopicitabine. Increases in mean AST, CK, pancreatic amylase and lipase were observed in the valopicitabine-containing arms (AST and CK subsequently decreased by the end of treatment in the triple combination arm); but these did not correlate with clinical adverse events. Conclusion: Valopicitabine combined with PegIFN/RBV demonstrated additive antiviral activity. HCV RNA PCR-negativity rates at all timepoints were consistently greater in the triple regimen compared with PegIFN/RBV. However, the incidence of GI-related adverse events and lab abnormalities was higher in the valopicitabine-containing arm. After comprehensive review of the valopicitabine clinical program, the development of this molecule has been discontinued due to its overall risk/benefit profile.

**1399 SONIC HEDGEHOG IS AN AUTOCRINE VIABILITY FACTOR FOR MYOFIBROBLASTIC HEPATIC STELLATE CELLS**

Liu Yang¹, Ying Wang¹, Hua Mao¹, Susanne Fleig², Alessia Omenetti¹, Kevin Brown¹, Jason K. Sicklick¹, Yin-Xiong Li³, Anna Mae Diehl⁴; ¹Medicine, Division of Gastroenterology, Duke University Medical Center, Durham, NC, ²Surgery, Johns Hopkins University School of Medicine, Baltimore, MD

Background/Aims: Factors released during liver injury, such as platelet derived growth factor-BB (PDGF) promote the accumulation of myofibroblastic hepatic stellate cells (MF-HSC) that play a pivotal role in the pathogenesis of cirrhosis. The Hedgehog pathway regulates remodelong of other injured tissues. Our aim was to evaluate the hypothesis that autocrine production of Sonic hedgehog (Shh) promotes MF-HSC growth. Methods: Primary rat HSC were cultured and treated without or with PDGF, a pharmacologic inhibitor of PDGF-regulated kinases, adenovirus expressing activated or dominant negative AKT, or Hedgehog signaling inhibitors. Shh production and HSC growth were assessed. Results: By day 7 during spontaneous culture-induced activation, HSC produced 6 fold more biologically active Shh protein than freshly isolated HSC (P<0.05). Neutralizing Shh antibodies activated caspases 3/7(P<0.05 vs control IgG) and induced apoptosis of cultured HSC. Adding PDGF(20ng/ml) to culture-activated HSC further increased expression of Shh mRNA and protein (both P<0.05 vs untreated) and enhanced MF-HSC growth (BrDU incorporation 5-fold increased, P<0.01). Both of the latter processes followed activation of AKT and were abrogated by AKT inhibitors. Even without exogenous PDGF, adenoviral delivery of activated AKT up-regulated Shh expression 6 fold (P<0.05 vs control adenovirus), demonstrating a direct role for AKT in regulating Shh expression in HSC. Moreover, Shh neutralizing antibodies and other Hh pathway inhibitors (cyclopamine and A99944) reduced the mitogenic actions of PDGF by at least 50% (P<0.05 vs control). Conclusion: These results identify Shh as an
autocrine growth factor for MF-HSC and suggest a role for HH signaling in the pathogenesis of cirrhosis.

1400 AUTOCRINE SIGNALING BY SDF-1α THROUGH ITS RECEPTOR, CXCR4, MEDIATES HEPATIC STELLATE CELL ACTIVATION IN VIVO AND IN VITRO

Feng Hong, Ana Tuyama, Ritu Agarwal, Ritu Gupta, Xin Cheng, Anita Garg, Yukiko Inoue, M. Isabel Fiel, Myron Schwartz, Martina Schwarzkopf, Alison D. Schecter, Meena B. Bansal; Mount Sinai School of Medicine, New York, NY

Chemokine interactions with their receptors have been implicated in hepatic stellate cell (HSC) activation. The hepatic expression of CXCR4 is increased in Hepatitis C (HCV)-cirrhotic livers and plasma levels of its endogenous ligand, Stromal-derived factor-1α (SDF-1α), correlate with increased fibrosis in these patients. The expression of CXCR4 by HSCs has not been reported. We hypothesize that HSCs express functional CXCR4 and that receptor engagement by SDF-1α promotes HSC activation, fibrogenesis and proliferation. Methods: To determine whether activated HSCs express CXCR4 in vivo, human liver biopsy specimens from HCV patients were examined for co-expression of CXCR4 and α-SMA using confocal microscopy. Expression of CXCR4 mRNA, protein, and surface expression in LX2 cells, a HSC line, was determined by RT-PCR, Western, and FACS analyses, respectively. Primary HSCs isolated from normal liver were culture-activated and CXCR4 expression examined by sequential FACS analyses. To explore the functional role of CXCR4 on stellate cells, LX2 cells were treated with SDF-1α and expression of α-SMA by Western, collagen I expression by qRT-PCR, and proliferation by 3H thymidine incorporation were examined. Involvement of the ERK1/2 signaling pathway, known to be important in HSC biology, was characterized by treating cells with SDF-1α or diluent (+/- AMD3100, a CXCR4 inhibitor) and immunoblotting for phospho-ERK1/2. ELISAs for SDF-1α were performed on media from both LX2 and primary HSCs. Effect of TGFβ1, a potent fibrogenic cytokine, on CXCR4 expression in LX2 and primary HSCs was examined by Western and FACS. Results: Activated HSCs express CXCR4 in vivo in patients with HCV. Both LX2 and primary HSCs express CXCR4 which increased with progressive culture-induced activation. SDF-1α (100-1000ng/ml) induced: α a dose-dependent increase in α-SMA expression (p<0.005); b) a 2-fold increase in collagen I (α1) mRNA expression (p<0.007); and c) a significant increase in proliferation (p<0.05) in LX2 cells. SDF-1α stimulates CXCR4-dependent ERK-1/2 phosphorylation, as increases were blocked by AMD3100 pretreatment. TGFβ1 increased CXCR4 expression (>2-fold; p<0.005) in HSCs at all stages of activation. LX2 and primary HSCs produce SDF-1α implicating both paracrine and autocrine regulation of HSC activation via CXCR4. Conclusions: 1) Activated HSCs express functional CXCR4 receptor in vivo and in vitro; 2) CXCR4 receptor activation by SDF-1α is pro-fibrogenic through its effects on HSC activation, fibrogenesis, and proliferation. 3) The availability of small molecule inhibitors of CXCR4 make this receptor a novel target for antifibrotic approaches.

1401 HUMAN AND RAT HEPATIC STELLATE CELLS EXPRESS OPIOID RECEPTORS AND ARE STIMULATED BY ENDOGENOUS OPIOID PEPTIDES IN A PARACRINE MANNER

Gianluca Svegliati-Baroni1, Cinzia Candelaresi1, Tania Roskams2, Samuele De Minicis2, Stefania Saccamanno1, Nicola Cautero3, Salzano Renato4, Fabrizio Di Francesco2, Marco Marzioni3, Alessandro Casini4, Andrea Risaliti3, Antonio Benedetti1; 1Gastroenterology, Polytechnic University of Marche, Ancona, Italy; 2Morphology and Molecular Pathology, University of Leuven, Leuven, Belgium; 3Hepatobiliary and liver transplant surgery, Polytechnic University of Marche, Ancona, Italy; 4Nutrition Center and GI Unit, University of Florence, Florence, Italy

Background: Endogenous opioid peptides (EO) modulate the growth of nervous and non-nervous cells. Hepatic stellate cells (HSC) are the main cell phenotype involved in liver fibrogenesis, they display molecular markers of nervous cells and respond to neurotransmitters. Aim: to evaluate the eventual effect of EO on human HSC (hHSC) biology and liver fibrogenesis. Methods: hHSC were isolated from excess liver after colonic metasases resection, rat HSC (rHSC) from normal rats. Human liver biopsies were obtained from patients with chronic liver diseases. Liver fibrosis was induced in rats by dimethylnitrosamine (DMN) administration. Results: By western blot and reverse transcriptase-PCR, quiescent and activated hHSC and rHSC expressed the “classical” opioid receptor isoforms (DOR, MOR, and KOR). Opioid receptor activation by specific agonists increased hHSC and rHSC proliferation and type I collagen synthesis. By using specific intracellular kinase inhibitors, these effects were induced through a calcium-dependent PKCα/ERK1/PI3K pathway activation. The general opioid receptor antagonist naloxone blocked the effect of EO on HSC proliferation and type I collagen synthesis, with no effects on either PDGF-induced proliferation or TGFβ1-induced type I collagen accumulation, confirming that the effects of EO on HSC were mediated by a specific agonist-receptor interaction. In the course of human cholestatic liver diseases, cholangiocytes synthesize met-enkephalin, the most important endogenous opioid peptide. Met- enkephalin was also expressed by hepatocytes in liver biopsies of patients with chronic hepatitis C and alcoholic liver diseases. Furthermore, parenchymal met-enkephalin expression in the DMN model of hepatic fibrosis preceded the process of rHSC activation. In liver samples from both human and rat chronic liver diseases, opioid receptors co-localized with alpha-smooth muscle actin (α-SMA) and glial fibrillar acidic protein (GFAP), as markers of hHSC and rHSC respectively. Finally, met- enkephalin induced cell proliferation and type I collagen synthesis in both hHSC and rHSC. Conclusions: In chronic liver diseases, the cellular targets of the hepatic injury produces the main endogenous opioid peptide, met- enkephalin. The synthesis of met-enkephalin in an experimental model of hepatic fibrosis precedes the process of HSC activation. In liver samples from both human and rat chronic liver diseases, opioid receptors co-localized with alpha-smooth muscle actin (α-SMA) and glial fibrillar acidic protein (GFAP), as markers of hHSC and rHSC respectively. Finally, met- enkephalin induced cell proliferation and type I collagen synthesis in both hHSC and rHSC. Conclusions: In chronic liver diseases, the cellular targets of the hepatic injury produces the main endogenous opioid peptide, met- enkephalin. The synthesis of met-enkephalin in an experimental model of hepatic fibrosis precedes the process of HSC activation towards a myofibroblastic phenotype. The expression of opioid receptors and the effect of met-enkephalin on hHSC and rHSC indicates that EO stimulate in a paracrine manner the process of hepatic fibrogenesis during chronic liver injury.

EFFECT OF SIMULATED MICROGRAVITY ON RAT HEPATIC STELLATE CELLS AND THEIR INTERACTION WITH EXTRACELLULAR MATRIX PROTEINS
Kota N. Gopalakrishna, Bruce Luxon; GI Division, University of Iowa, Iowa City, IA

Background: Hepatic stellate cells (HSC) are the major cell type responsible for liver fibrosis. HSC become activated when plated on plastic and express activation markers such as smooth muscle actin (SMA) and procollagen A (PCA). It is recognized that cells grown in a two-dimensional environment tend to dedifferentiate and lose the specialized features of their original tissues. In this study we used a rotary cell culture system (RCCS) to produce a 3D culture of HSC which more closely mimics the in vivo situation. RCCS produces a microgravity-like environment in which HSC undergo free-fall as they rotate and form aggregates of cells.

Aim: To analyze gene expression of HSC activation in 3D environment in simulated microgravity for quiescent and chronically activated HSC.

Methods: HSC were isolated from male Sprague-Dawley rats by pronase collagenase digestion followed by sucrose density gradient centrifugation. HSC were plated on plastic in Ham's DMEM media and trichrome staining of 10 day microgravity aggregates of HSC was performed. In situ perfusion of rat liver was performed. The hepatic capsule was removed and hepatic parenchymal tissue was mechanically dissociated from portal tracts. Portal tract tissue was dispersed and subsequently plated on type I collagen. Primary PF were cultured using an explant-culture technique for 72 h. The

Results: Quiescent and activated HSCs express both isoforms of the insulin receptor and about 1.5 times more IRS2 than IRS1. Interestingly, we observed that protein steady state levels of the insulin receptor, but not its corresponding mRNA, were downregulated with increasing concentrations of insulin in the culture medium. Expression of IRS3, IRS4 and GLUT4 was very weak. Insulin induces phosphorylation of AKT in quiescent and activated HSCs, but nearly no phosphorylation of ERK1/2. Moreover, insulin causes no significant increase in the gene expression of the transcription factor SREBP-1c and the lipogenic enzyme fatty acid synthase. Other typical insulin responsive genes such as PEPCK, glucokinase and the transcription factor HNF-4α were poorly expressed in the absence and presence of insulin. In addition, we did not find a direct effect of insulin on α-SMA, a positive marker for HSC activation and GFAP, a negative marker. Conclusions: Although the main components of the insulin receptor signaling pathways are present in mouse HSCs, transcription of genes, known to be affected by insulin in other cell types, was not affected. This suggests the presence of one or more negative regulators of the insulin signaling pathways, and hence insulin resistance of mHSCs, which is enhanced by downregulation of the receptor under the influence of its ligand. The mechanism by which insulin receptor protein decreases following exposure to insulin is the current focus of our research.

MOUSE HEPATIC STELLATE CELL INSULIN RESISTANCE IS CAUSED BY DOWNREGULATION OF INSULIN RECEPTOR PROTEIN AND DEFECTIVE DOWNSTREAM SIGNALING
Sara Knops1; Leo A. van Grunsven1, Hendrik Reynaert1, Albert Geerts1; 1Department of Cell biology, Vrije Universiteit Brussel, Brussels, Belgium; 2Department of Gastroenterology-Hepatology, Vrije Universiteit Brussel, Brussels, Belgium

Background & aims: NAFLD is characterized by the occurrence of insulin resistance and hyperinsulinemia. In the progression of this disease, activated hepatic stellate cells (HSCs) play an important role. We investigated insulin signaling in mouse HSCs and the effects of insulin on HSC activation. Methods: Transdifferentiation of HSCs was obtained by culturing primary mouse HSCs on polystyrene dishes in presence of 10% fetal bovine serum. Quiescent 2-day cultured cells were compared with activated 13-day old HSCs. The presence of key molecules of the insulin receptor signaling pathways was determined by quantitative RT-PCR and Western blot. Effects of different insulin concentrations (1-100 nM) on HSC activation and on the activation of the PI3K- and MAPK-pathway were investigated. Results: Quiescent and activated HSCs express both isoforms of the insulin receptor and about 1.5 times more IRS2 than IRS1. Interestingly, we observed that protein steady state levels of the insulin receptor, but not its corresponding mRNA, were downregulated with increasing concentrations of insulin in the culture medium. Expression of IRS3, IRS4 and GLUT4 was very weak. Insulin induces phosphorylation of AKT in quiescent and activated HSCs, but nearly no phosphorylation of ERK1/2. Moreover, insulin causes no significant increase in the gene expression of the transcription factor SREBP-1c and the lipogenic enzyme fatty acid synthase. Other typical insulin responsive genes such as PEPCK, glucokinase and the transcription factor HNF-4α were poorly expressed in the absence and presence of insulin. In addition, we did not find a direct effect of insulin on α-SMA, a positive marker for HSC activation and GFAP, a negative marker. Conclusions: Although the main components of the insulin receptor signaling pathways are present in mouse HSCs, transcription of genes, known to be affected by insulin in other cell types, was not affected. This suggests the presence of one or more negative regulators of the insulin signaling pathways, and hence insulin resistance of mHSCs, which is enhanced by downregulation of the receptor under the influence of its ligand. The mechanism by which insulin receptor protein decreases following exposure to insulin is the current focus of our research.

purity of cells was assessed by immunocytochemistry with fibulin-2 for liver fibroblasts, GFAP (glomerular fibrillary acidic protein) for HSCs, and CK-19 for cholangiocytes. Cytokine microarray was performed with culture supernatants from both PF and HSCs and compared by quantitative assay. Differences in expression of key cytokines were confirmed by extracting cell lysates and performing immunoblot analysis. RESULTS: PF were confirmed in culture by positive immunostaining with fibulin-2; PF cells were both GFAP and CK-19 negative. Conversely, lobular HSCs stained negative for fibulin-2 and positive for GFAP. In the initial cytokine array analysis, we designed a platform and tested nineteen of the most common cytokines associated with liver fibroblast biology. When compared to HSCs, PF arrays demonstrated significant overexpression of TIMP-1 (tissue inhibitor of metalloproteinase-1), VEGF (vascular endothelial growth factor), MCP-1 (monocyte chemoattractant protein-1), and CINC-2 and CINC-3 (cytokine-induced neutrophil chemoattractant). Immunoblot with antibodies to these proteins confirmed increased expression in fibulin-2 positive cells when compared to GFAP-positive, fibulin-2 negative cells. CONCLUSIONS: This study indicates that successful isolation and culture of PFs demonstrate key biologic differences between PF and HSCs. Importantly, cytokine array is a useful way to further distinguish key physiological differences with lobular myofibroblasts since upon activation such cells secrete a large number of cytokines. Such differences in biologic profiling may account for the mechanism of enhanced biliary fibrosis in rodent models.

NOX2 AND RAC1 PLAY IMPORTANT ROLES IN LIVER FIBROGENESIS BY FACILITATING PHAGOCYTOSIS OF APOPTOTIC BODIES AND PRODUCTION OF ROS BY STELLATE CELLS

Joy Jiang, Kornelia Baghy, Natalie Torok; Gastroenterology and Hepatology, UCDMC, Sacramento, CA

We have previously shown that hepatic stellate cells (HSC) are activated by the phagocytosis of apoptotic bodies (AB) from hepatocytes. Phagocytosis induces NADPH oxidase (NOX) resulting in production of superoxide (O2-) and pro-collagen α 1(I) upregulation. As NOXs are central to the fibrogenic process, and NOX2 is described as the phagocytic NOX, our hypothesis is that NOX2 activation plays a role in phagocytosis of AB and subsequent O2- production. Furthermore, the small GTP-ase Rac1, a regulatory element of NOXs could also involved in phagocytosis of AB, and in downstream signaling leading to HSC activation. Methods: Primary rat HSC were transfected with NOX2-specific siRNA, exposed to AB, and the phagocytic rate, O2- production (lucigem assay) and the pro-collagen α 1(I) expression (real-time PCR) were tested. NOX2-dependent Rac1 activation was evaluated by the Rac-GTP pull-down assay after exposing HSC to AB in the presence or absence of 100 μM apocynin (NOX inhibitor), or 20 μM LY294002 (PI3K inhibitor). LX-2 cells were transfected with the constitutively active Rac1 (G63L), then exposed to AB and the rate of phagocytosis, and changes in the actin cytoskeleton (phallolidin staining) were evaluated. Results: The rate of phagocytosis in NOX2 siRNA-treated cells decreased to 0.70-fold (±0.20), compared to scrambled siRNA-transfected cells. The O2- production of NOX2 siRNA transfected-cells decreased to 0.41-fold (±0.11) and the pro-collagen α 1(I) expression to 0.64-fold (±0.32). Phagocytosis of AB induced Rac1 GTP-ase activation, and this was inhibited by apocynin suggesting that Rac1 activation occurs in concert with NOX2 activity. Inhibition of PI3K did not affect Rac1 activity. To determine if Rac1 is directly involved in the phagocytosis of AB, HSC were transfected with Rac1-Q63L, and we found that this increased the phagocytic rate by 1.65-fold (±0.16), when compared to cells transfected with the empty vector. There was also a significant reorganization in the actin cytoskeleton surrounding the phagosomes suggesting that Rac1 mediates its effects on phagocytosis via regulation of the actin cytoskeleton. In conclusion, NOX2 is involved in phagocytosis of AB by HSC and is responsible for O2- production and upregulation of procollagen α 1(I) expression. NOX-dependent Rac1 activation leads to an increase in phagocytosis with reorganization of the actin cytoskeleton in HSC, perpetuating the fibrogenic activity.

REGULATION OF HEPATIC STELLATE CELL GROWTH BY NUCLEAR AND CYTOSOLIC CALCIUM SIGNALS

Elwy M. Soliman, Michelle Rodrigues, Davidson A. Gomes, Jin Yu, Michael H. Nathanson, Jonathan A. Dranoff; Internal Medicine/Digestive Diseases, Yale University School of Medicine, New Haven, CT

Background. Hepatic stellate cells (HSC) are important mediators of liver fibrosis. Many HSC mitogens linked to calcium signals have been identified, yet the downstream mediators of HSC proliferation have not been well characterized. Recent data suggest that nuclear, but not cytosolic calcium signals are critical regulators of growth in hepatocytes. Thus, the aims of this project were to determine whether nuclear and/or cytosolic calcium was important in the regulation of HSC growth.

Methods. LX-2 spontaneously immortalized human hepatic stellate cells (kindly provided by Dr. Scott Friedman) were used for all studies. Blockade of calcium signals within nuclear and extranuclear compartments was obtained using plasmid constructs expressing the calcium chelator parvalbumin linked to either a nuclear-localization sequence or a nuclear exclusion-sequence and further linked to the fluorescence protein DsRed (PV-NLS-DsRed and PV-NESS-DsRed, respectively). LX-2 cells were transfected with DsRed alone, PV-NLS-DsRed, or PV-NESS-DsRed. Appropriate targeting of plasmids was determined using confocal microscopy to identify DsRed fluorescence. Determination of calcium signals was determined using confocal microscopy to observe fluo-4 fluorescence. Cell proliferation was assessed by bromo-deoxyuridine incorporation. Results. Transfection of LX-2 cells with constructs resulted in appropriate targeting of DsRed (throughout the cell), PV-NLS-DsRed (to the nucleus alone), and PV-NESS-DsRed (to the extra-nuclear cytosol). Calcium signals induced by extracellular ATP (100 μM) were not inhibited in cells transfected with DsRed. However, calcium signals induced by extracellular ATP were blocked only within the nucleus in LX-2 cells transfected with PV-NLS-DsRed, and calcium signals induced by extracellular ATP were blocked only within the cytosol in LX-2 cells transfected with PV-NESS-DsRed. LX-2 proliferation was not changed in cells transfected with DsRed alone. However, LX-2 proliferation was decreased to 21.2% of control (p < 0.0001) in LX-2 cells transfected with PV-NLS-DsRed and to 60.5% (p < 0.0005) in LX-2 cells transfected with PV-NESS-DsRed (n = 10).

Conclusions. Hepatic stellate cell mitogens acting via calcium signals do so in a fashion distinct from hepatocyte mitogens, since both nuclear and extranuclear calcium are important in this process. The signal
transduction mechanisms by which these processes occur have yet to be defined.

APOTOPIC HEPATOCYTE DNA INHIBITS HSC CHEMOTAXIS AND STIMULATES HEPATIC STELLATE CELL DIFFERENTIATION VIA TLR9
Azuza Watanabe1, Ardeshir Hashmi1, Davidson Gomes1, Terrence Town2, Abdallah Badou2, Muhammad A. Sohail1, Richard A. Flavell2, Wajahat Z. Mehali1; 1Centre for Hepatology, University College London, London, United Kingdom; 2Surgery, North Hampshire Hospital, Basingstoke, United Kingdom; 3Gastroenterology, Guy’s and St Thomas’ Hospital, London, United Kingdom
Background: Hepatocyte apoptosis is known to result in hepatic stellate cell (HSC) differentiation, but the molecular signals are not well defined. Mammalian DNA from apoptotic cells is enriched in Cpg motifs, and can activate B cells via TLR9. We hypothesized that apoptotic mammalian DNA can activate HSC via TLR 9. Methods: cDNA was prepared from human HSC line LX-2 and mouse HSC and amplified with primers specific for TLR9. LX-2 cells and primary mice HSC were cultured with CpG (5µg/ml), apoptotic DNA (50µg/ml) or healthy DNA (50µg/ml). After 24 hours, quantitative real time PCR was performed for TGF-β and collagen1, and western blotting for α-smooth muscle actin. We tested the ability of apoptotic DNA to inhibit PDGF induced HSC chemotaxis, and tested if the mechanism of TLR9 inhibition of PDGF induced increase in cytosolic Ca2+ was by inhibition of IP3 mediated signaling. We performed intra-peritoneal injection for carbon tetrachloride (CCl4) (850µl/kg) to wild-type and TLR9 KO mice for 8 weeks. Liver samples were stained with Sirius Red. Results: LX-2 cells and mouse HSC express mRNA for TLR9. TLR9 agonist and mammalian DNA from apoptotic hepatocytes induce up-regulation of TGF-β and collagen1 mRNA, and inhibited PDGF induced chemotaxis. These effects are blocked by TLR9 antagonist and were not present in TLR9 KO mice. TLR9 agonist induces up-regulation of α-smooth muscle actin by western blotting. Activation of TLR9 prior to exposure to PDGF significantly diminished the peak and plateau of the increase in cytosolic Ca2+ (P<0.02). Pre-treatment of LX-2 cells with apoptotic hepatocyte DNA inhibited IP3 mediated increase in cytosolic Ca2+. TLR9 KO mice compared to wild-type had significantly reduced CCI4 induced liver fibrosis. Conclusions: Apoptotic mammalian DNA can signal cellular apoptosis to HSC via TLR9, resulting in actin reorganization, inhibition of chemotaxis and HSC differentiation.

SYMPATHETIC NERVOUS SYSTEM SIGNALLING IN HUMAN PRIMARY HEPATIC STELLATE CELLS: A NOVEL ANTI-FIBROTIC PATHWAY
Barbara Sigala1, Florence Potter1, Clare Selden1, Myrddin Rees2, Anthony Wierzbicki3, Humphrey J. Hodgson1, Jude A. Oken1,3; 1Centre for Hepatology, University College London, London, United Kingdom; 2Surgery, North Hampshire Hospital, Basingstoke, United Kingdom; 3Gastroenterology, Guy’s and St Thomas’ Hospital, London, United Kingdom
Background: Emerging evidence suggests that sympathetic nervous system (SNS) signalling regulates hepatic fibrogenesis. Mouse hepatic stellate cells (HSC) synthesize and release the SNS neurotransmitter (SNSNT), norepinephrine (NE) and are regulated by NE in culture. Mice lacking NE have impaired fibrogenic responses. The relevance of these animal studies to human fibrogenesis is unclear. Aim: To investigate the effects of the SNSNTs NE and neuropeptide Y (NPY) on human primary HSC (hHSC) proliferation, collagen gene expression and release of pro-fibrogenic cytokines. Methods: Primary hHSC were isolated from healthy liver segments of patients (n=3) undergoing resection of metastases. Quiescent hHSC autofluoresced, with abundant expression of glial fibrillary acidic protein (GFAP). Myofibroblastic transformation in culture reduced GFAP and increased α-smooth muscle actin plus collagen-α1 expression. hHSC conditioned media was analyzed for NE by HPLC. RNA was extracted from hHSC and analyzed for expression of adrenergic receptors by QRT-PCR. Basal proliferation of hHSC with, time in culture, prazosin (PRZ, α1-adrenoceptor antagonist) or propranolol (PRL, β-adrenoceptor antagonist), or stimulated by NPY and NE+PRZ/PRL was assessed by a colorimetric, tetrazolium assay. Apoptosis was assessed by annexin V. Involvement of intracellular pathways was assayed by culture of hHSC with NE or NPY in the presence of specific inhibitors: pertussis toxin(G-protein inhibitor); wortmannin(Pi3-kinase inhibitor); SB202190(p38 MAP kinase inhibitor); PD98059(MEK inhibitor) and RO-32-0432(Protein kinase C inhibitor). Induction of collagen-α1 gene by NE or NPY was assessed by RT-PCR. To see if NE and NPY induced collagen expression directly, interleukin (IL)-4, IL-13, leptin and transforming growth factor-β1 were assayed by ELISA. Results: hHSC synthesize, release NE and express α1A, β1, β2, β3 adrenoceptors. NE is an autocrine growth and survival factor since basal growth and survival is reduced by PRZ±PRL by ≥50%, p<0.05. Time reduces basal proliferation: cells at day30 cells grow less than day15 (p<0.001). PRZ inhibited exogenous NE induced hHSC proliferation by 80±5%, p<0.02. NE and NPY induced hHSC proliferation involves p38 MAP kinase and Pi-3 kinase respectively. NE but not NPY induced collagen gene expression through TGF-β1 with no involvement of IL-4, IL-13 or leptin. Conclusion: hHSC synthesize, release NE and express α1A, β1, β2, β3 adrenoceptors. PRZ inhibits NE induced hHSC proliferation. NPY induces hHSC growth through Pi-3 kinase. NE but not NPY upregulates collagen gene expression through TGF-β1. SNS signalling is a novel anti-fibrogenic pathway in humans.

ENDOGLIN PHOSPHORYLATION BY TGF-β RECEPTORS IN TRANSDIFFERENTIATING HSC
Steffen K. Meurer, Wanda N. Vreden, Lidia Tihaa, Axel M. Gressner, Ralf Weiskirchen; Inst. of Clinical Chemistry and Pathobiocchemistry - Central Laboratory, RWTH University Hospital, Aachen, Germany
Background: Transdifferentiation of hepatic stellate cells (HSC) is regulated by two different TGF-β type I receptors, i.e. ALK5 and ALK1. In endothelial cells it has been shown that endoglin modulates signaling via these two type I receptors in an opposite manner. The functional interplay of endoglin with the TGF-β type II and type I receptor (ALK1) at the surface of the cell is characterized by specific phosphorylation of the C-terminal domain of endoglin by these receptors which in turn modulate the function of endoglin. When the receptor is internalized type II receptor serine-phosphorylation is lost. We have previously...
shown that endoglin is highly expressed in HSC and that it is exposed on the surface. Results: We show here that endoglin is engaged in a TGF-β1 binding receptor-complex in rat HSC by TGF-β1 cross linking experiments. To monitor a direct interaction of these receptors we analyzed the serine phosphorylation of endoglin by the TGF-β type II receptor at the C-terminus of rat endoglin (ser-626/ser-627). By this approach we could demonstrate a strong phosphorylation of endoglin in early and late HSC which declines sharply in MFB. Experiments with siRNA to endoglin in HCS and reconstitution of this receptor system in COS-7 cells confirmed the specificity of this RII phosphorylation. In addition the surface expression of RII paralleled that of the endoglin phosphorylation which in turn may reflect at least in MFB the insensitivity to TGF-β. Furthermore RII phosphorylated endoglin is not exclusively exposed at the surface, because no biotinylated endoglin could be precipitated from surface biotinylated cells cultured for 1 day or 2 days, although these cells showed a high amount of phosphorylated endoglin. On the other hand in MFB we could detect significant amounts of endoglin in the membrane but only a marginal phosphorylation level. Conclusion: We conclude that endoglin is involved in TGF-β signaling in HSC as could be demonstrated by binding of the ligand and phosphorylation by the type II receptor. The corresponding type one receptor involved is most likely ALK1, because we found that a population of the serine phosphorylated endoglin is in addition threonine phosphorylated by immunoprecipitation experiments. Finally we speculate that the surface exposed endoglin in MFB fulfills a function which is independent of TGF-β.

MESENCHYMAL β-CATENIN SIGNALING REGULATES HEPATIC STELLATE CELL FATE

Tove A. Berg, Stijn De Langhe, Joaquin J. Estrada, Hidekazu Tsukamoto, Saverio Belluscio, Kasper Wang; Saban Research Institute, Los Angeles, CA

Background: In the adult liver, differentiation of quiescent hepatic stellate cells (HSCs) to activated, extracellular matrix and growth factor-producing myofibroblastic cells in part supports liver regeneration through promotion of hepatocyte proliferation. In the embryonic liver, fibroblast growth factor (FGF) 10 is secreted by embryonic hepatic stellate cells (HSC) and activates the canonical WNT signaling pathway in hepatoblasts to maintain their proliferation (Berg et al., Hepatology, 2007). We also observe the similar paracrine role of HSC-derived FGF-10 in adult liver regeneration after partial hepatectomy (Estrada et al., in progress). Previously we have shown that mesenchymal β-catenin signaling play an important role in expanding the pool of Fgf10 expressing mesenchymal progenitor cells (De Langhe et al., unpublished). Aim: To further characterize the development of embryonic HSCs, we used mice in which β-catenin expression is abrogated in the mesenchyme with the use of the mesenchymal specific Derm-1 promoter. Results: Dermo1-Cre+/-/β-cateninflox/- conditional knockout (CKO) embryos largely phenocopy Pitx1-/-/Pitx2-/- double knockout embryos (De Langhe et al., unpublished), and exhibit smaller livers with defective architecture, characterized by larger blood vessels located more proximally similar to that of Pitx2-/- mice. We find in the embryonic liver, that lack of mesenchymal β-catenin signaling leads to a differentiation of embryonic HSCs into myofibroblasts characterized by increased smooth muscle actin and collagen type I expression. CKO embryonic livers also feature abnormal and leaky blood vessels with pools of blood visible within the liver. This phenotype correlates with an increase in Flik1 expression, indicating a defect in blood vessel maturation. Conclusion: Based on our results, we speculate that embryonic stellate cells typically manifest canonical WNT activation, which is critical for normal liver and HSC differentiation and development.

MOUSE HEPATIC STELLATE CELLS EXPRESS THE INTERMEDIATE FILAMENT PROTEIN SYNCOILIN
Elke Van Rossen1, Zhenan Liu1, Leo A. van Grunsven1, Jona Van der Straeten1, Jan Van Daele2, Hendrik Reynaert1,2, Jean-Pierre Timmermans2, Albert Geerts1; 1Department of Cell Biology, Vrije Universiteit Brussel, Jette, Belgium; 2Department of Pharmacology, University of Cambridge, Cambridge, United Kingdom; 2Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

Background: Hepatic stellate cells (HSCs) are important in several (patho)physiological conditions. In response to chronic injury, HSCs are activated and change from quiescent to myofibroblast-like cells with contractile properties. This makes HSCs an interesting target in the study of portal hypertension. The shift in phenotype is accompanied by a dramatic change in expression of intermediate filaments (IFs). In contrast to most differentiated cell types, HSCs express a broad, but variable spectrum of IFs. Aim: Investigate the expression and functions of the IF protein syncoilin in HSCs. Methods: Syncoilin expression in isolated and cultured mouse HSCs was studied by quantitative reverse transcription polymerase chain reaction, Western blotting, and fluorescence immunocytochemistry (confocal microscopy). We generated different syncoilin antibodies for these purposes. The function of syncoilin in HSC contraction was studied by means of optical recording using the fluorescent calcium indicator, Fluo-4. Results: Syncoilin mRNA was present in HSCs, skeletal muscle, heart, brain, and stomach and was upregulated during HSC activation. While in quiescent HSCs no syncoilin protein could be detected, this protein was strongly upregulated during in vitro activation. We verified the cellular localization of syncoilin using immunocytochemistry. We observed filamentous staining in HSCs undergoing in vitro transdifferentiation. The syncoilin IF bundles did not colocalize with alpha smooth muscle actin or desmin filaments. To assess the function of syncoilin we performed calcium measurements in HSCs transfected with control or syncoilin siRNAs. In cells transfected with syncoilin siRNA, intracellular calcium release following stimulation with endothelin-1 was reduced. Conclusion: To our knowledge, we are the first group to demonstrate the presence of the IF protein syncoilin in mouse HSCs. This IF protein is strongly upregulated during in vitro activation. We show that syncoilin is an important player in intracellular calcium signaling.

ATRIAL NATRIURETIC PEPTIDE (ANP) PREVENTED LIVER FIBROSIS IN RAT USING NEW TREATMENT SYSTEM
Noriko Ishigaki, Naoki Yamamoto, Haiyan Jin, Koichi Uchida, Shuji Terai, Isa Sakaida; Department of Gastroenterology & Hepatology, Yamaguchi University, Graduate School of Medicine, Yamaguchi University, Ube city, Japan

[Aim/Background]: The atrial natriuretic peptide (ANP) has been used as the acute heart failure treatment in clinical and it is reported the suppression of fibrosis in the heart and the lung recently. The aim of this study was to examine the preventive effect of atrial natriuretic peptide (ANP) on liver fibrosis both in vitro and in vivo using new continuous infusion pump treatment system. [Methods]: In vitro, isolated hepatic stellate cells (HSC) were treated with ANP (0, 10, 50, 100 µg/ml). We examined α-SMA (alpha smooth muscle actin) expression by Western blot analysis and fibrotic gene mRNA expression was analyzed by RT-PCR. In vivo, Wister rats were injected with dimethylthiourea (DMN) twice a week via intraperitoneal injection (i.p.) for 4 weeks to develop the liver fibrosis. After one-week treatment with DMN, rats were randomly divided to three groups (each group n=6); Then rats were treated with ANP (0=saline, 0.1 and 1.0 mg/kg/min) using 24 hour continuous infusion pump for another 3 weeks. At the end of the study, the percent area of liver fibrosis, α-SMA-positive lesions were measured with computer analyzing system. [Results]: In vitro study, expression of α-SMA, type I collagen and TIMP-1 mRNA was inhibited with ANP in a dose-dependent manner. In vivo study, high dose ANP treated group showed significantly decreased serum AST (mean value: 81.8 vs 2000 IU/l, P<0.01) and ALT level (mean value: 63.8 vs 2000 IU/l, P<0.01). ANP significantly (P<0.01) decreased liver fibrosis area as well as α-SMA-positive lesions in a dose-dependent manner. In whole liver, ANP significantly inhibited type I collagen, MMP2 and TIMP-1 mRNA expression. [Conclusion]: Our results showed that the atrial natriuretic peptide (ANP) inhibited liver fibrosis by direct inhibition of hepatic stellate cell activation and with hepatocyte protection.

THE SYNTHETIC COLLAGEN ANALOG (GPO)10 STIMULATES PROLIFERATION, MIGRATION AND EXPRESSION OF N-CADHERIN IN HEPATIC STELLATE CELLS VIA ACTIVATION OF PROMMP-2
Christian Freise1, Martin Ruehl1, Marion Seja1, Ulrike Erben1, Richard Farndale2, Detlef Schuppan2, Martin Zeitz1, Rajan Sundaram3; 1Gastroenterology/Hepatology, Charité-Campus B.Franklin, Berlin, Germany; 2Department of Pharmacology, University of Cambridge, Cambridge, United Kingdom; 2Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

Introduction: Matrixmetalloproteinase-2 (MMP-2) degrades denatured collagens and plays a key role in liver fibrogenesis and fibrolysis. We previously showed that proMMP-2 binds to nonsubstrate collagens of the extracellular matrix and is released and activated by the collagen analog (GPO)10. The aim of this study was to elucidate cell specific events initiated by (GPO)10 induced proMMP-2 activation, such as proliferation, migration and expression of the HSC activation marker N-cadherin. Methods: (GPO)10 induced proMMP-2 activation was shown by gel zymography and substrate turnover. The hepatic stellate cell line CFSC was treated with nanomolar concentrations of zymogens and activated MMP-2 with and without specific MMP-inhibition (ilomastat) and (GPO)10. DNA neosynthesis was measured by [3H]thymidine incorporation. Additionally, a MMP-2 dependent migration assay was performed. N-cadherin expression was assessed by western-blotting. Results: A 10fold molar excess of (GPO)10 caused a complete activation of proMMP-2, whereas a control peptide showed no effect. Active MMP-2 and (GPO)10 stimulated CFSC proliferation up to 35 and 20% compared to maximum stimulated cells, respectively. The increase of proliferation induced by (GPO)10 activated endogenous MMP-2 was completely blocked with ilomastat. MMP-2 and (GPO)10 activated proMMP-2 specifically induced strong cell migration and upregulation of N-cadherin in HSC which was blocked by the addition of ilomastat. Conclusion: (GPO)10 activates proMMP-2 leading to enhanced proliferation, migration and activation of mesenchymal and hepatic stellate cells. Thus, (GPO)10 excerts
fibrolytic as well as fibrogenic effects. Animal studies will elucidate the role of this synthetic collagen peptide in liver fibrosis and regeneration.

CD95 Ligand Induces Proliferation and CD95-Tyrosine Nitration in Quiescent Rat Hepatic Stellate Cells

Roland Reinehr, Annika Sommerfeld, Stephan Becker, Dieter Haussinger; Gastroenterology, Hepatology and Infectiology, University Hospital Dusseldorf, Dusseldorf, Germany

Introduction: Quiescent hepatic stellate cells (HSC) are fairly resistant to CD95 ligand (CD95L)-induced apoptotic cell death, while apoptosis upon CD95L-treatment has been observed in activated HSC/myofibroblasts when cycloheximide (CHX) was co-administered (Cariers et al., Cell Physiol Biochem 2002). Recently, quiescent HSC have been reported to express CD133 and to represent a hepatic progenitor cell compartment (Kordes et al., BBRC 2007). Methods: Rat hepatic stellate cells were either cultivated for 1-2 days (quiescent HSC) or 10-14 days (activated HSC) on plastic culture dishes. Activation of Src, EGFR, Erks and JNks were measured by W. blot using respective phospho-specific antibodies. CD95 was immunoprecipitated and detected for CD95/EGFR-association, CD95-tyrosine phosphorylation, CD95-tyrosine nitration and DISC-formation using W. blot technique. HSC proliferation and apoptosis were analyzed by BrdU-incorporation measurements and TUNEL-staining, respectively. Results: In quiescent HSC, CD95L leads to an activation of c-Src, EGFR and Erks which was sensitive to inhibitors of Src-kinases (PP-2), sheddases (GM6001) and to EGF-neutralizing antibodies, while no JNK-activation occurred. Furthermore, an increased bromodesoxyuridine incorporation was observed in quiescent HSC after CD95L-Addition, while no pro-apoptotic CD95-activation became detectable with respect to CD95/EGFR-association, CD95-tyrosine phosphorylation, DISC-formation, TUNEL-staining and PARP-cleavage. In addition, in quiescent HSC CD95L induced CD95-tyrosine nitration in a time- and dose-dependent manner, which was previously shown to inhibit CD95-tyrosine phosphorylation and thereby exhibits anti-apoptotic properties. In contrast, in activated HSC no CD95-tyrosine nitration upon CD95L administration was observed, whereas there was still activation of the EGFR. When CD95L and CHX were co-administered, a sustained JNK-activation occurred which allowed for CD95/EGFR-association, subsequent CD95-tyrosine phosphorylation, DISC formation and apoptotic cell death. Conclusions: In quiescent HSC, CD95L is a mitogen through a ligand-dependent activation of the EGFR which requires Src-kinase- and sheddase-activity. Simultaneously, apoptotic signaling is prevented by CD95L-induced CD95-tyrosine nitration, which may contribute to the recently described progenitor cell properties of quiescent HSC and which is lost after differentiation to activated HSC/myofibroblasts.

Inhibition and Identification of Nonmuscle Myosin II Isoforms in Hepatic Stellate Cells

Cathy C. Moore, Christopher M. Yengo, Laura W. Schrum; Biology, UNC-Charlotte, Charlotte, NC

Regulation of liver microcirculation is a complex system where blood flow is under systemic and sinusoidal control. Under normal conditions, quiescent hepatic stellate cells (HSC) wrap around sinusoids to regulate diameter, and thus blood flow, by contracting and dilating in response to local vasconstrictors and vasodilators. However, activated HSCs exert a sustained contractile force, resulting in hyper-constricted vessels. This leads to hepatic microcirculation dysregulation, which contributes to the progression of diseases such as fibrosis, hepatocellular carcinoma, or viral hepatitis. Nonmuscle myosin II (NMMy II) has been shown to be the motor protein involved in the contraction of HSCs; however, the expression levels and cellular localization of the specific isoforms (NMMy II-A, II-B and II-C) have not been characterized, nor has NMMy II been specifically blocked in activated HSCs. Blebbistatin is a novel chemical inhibitor which specifically blocks NMMy II activity. HSCs treated with blebbistatin in a collagen contraction assay inhibited vasconstrictor-induced contraction, as well as basal contraction. Cellular localization in activated HSCs visualized by immunocytochemistry demonstrated that NMMy II-A and II-B were localized to the periphery and actin stress fibers, while NMMy II-C protein expression was dispersed. The data are consistent with previous studies that suggest NMMy II-A and II-B function in cell migration and contraction, respectively. Using RT-PCR and Western blotting, in vitro data revealed robust mRNA and protein expression of NMMy II-B with lower expression levels of NMMy II-A and II-C in culture-activated HSCs. Additionally, protein expression of all three isoforms was undetectable in freshly isolated quiescent HSCs; however, minimal levels of mRNA were detected. As compared to normal liver, fibrotic tissue as visualized by immunohistochemistry showed increased staining of NMMy II-B in activated HSCs; however, NMMy II-A and II-C did not colocalize in HSCs even though expression of these isoforms was visualized in other cell types. In conclusion, our study demonstrates that NMMy II-B is strongly upregulated in activated HSCs. Since this isoform is known to spend a larger period of its ATPase cycle bound to actin than NMMy II-A and II-C, its enhanced expression may be responsible for inducing the hyper-contractile activity of HSCs. Determining the expression profile of NMMy II isoforms and their functional role in HSCs may lead to specific therapeutic targets in the treatment of liver diseases. Supported by NIH Grant AA14891.

Different Regulation of the Connective Tissue Growth Factor in Hepatic Stellate Cells and Hepatocytes

Lucia Wickert, Nicolas Chatain, Karin Kruschinsky, Axel M. Gressner; Inst. of Clinical Chemistry and Pathobiology - Central Laboratory, RWTH University Hospital, Aachen, Germany

Background: The connective tissue growth factor (CTGF), a CCN family protein is described as a down-stream modulator of proliferative TGF-β effects, e.g. in activating hepatic stellate cells (HSC) and promoting the deposition of extracellular matrix (ECM). CTGF has been demonstrated in experimental fibrosis, in which its expression appears to correlate with the degree of
fibrosis. The activation of HSC and the proximate ECM production are triggered by TGF-β. Active TGF-β binds and phosphorylates transmembrane receptors, which in turn propagate the signal via Smads into the nucleus in order to bind the appropriate promoter sequence of a target gene. CTGF expression could be induced by TGF-β as well as by glucocorticoids. Previous studies showed that glucocorticoids decrease TGF-β-sensitive reporter signalling in primary HSC. The aim of this study was to characterize the molecular effects of glucocorticoids and TGF-β on CTGF expression in primary HSC and hepatocytes and to ascertain the impact of glucocorticoid-TGF-β interaction. Results: Therefore, we analysed CTGF expression by a combined stimulation with dexamethasone and TGF-β in hepatocytes and HSC. We determined by western blots that CTGF was significantly induced in both cell types after co-stimulation with TGF-β and dexamethasone. It seems that different pathways for CTGF regulation were used in HSC and hepatocytes: Whereas TGF-β and dexamethasone induced CTGF is decreased when JNK function is inhibited in HSC, CTGF increased expression was repressed by Erk-inhibitor in hepatocytes. Interestingly, we observed a different CTGF secretion: It was directly secreted by activated HSC but selectively released into the culture medium by TGF-β-stimulated hepatocytes. Moreover, TGF-β and dexamethasone have antagonistic effects on Erk phosphorylation: TGF-β induce it, dexamethasone abrogate it. Our data suggest that the cell-type specific regulation seems to be dependent on MEK, which decide between a downstream signalling via Erk or via JNK. Conclusions: CTGF expression control is accomplished by the use of the TGF-β-Smad and the TGF-β-Ras-Mek pathway in a cell-type specific manner and our data indicate that a complex signalling network regulate the fine tuning of expression and secretion in HSC and hepatocytes.

1418 RELAXIN INCREASES THE EXPRESSION AND ACTIVITY OF PPARγ IN ACTIVATED HEPATIC STELLATE CELLS
Robert Bennett1,2, Dean J. Tuma1,2; 1Medical Research, VA Medical Center, Omaha, NE; 2Internal Medicine, University of Nebraska Medical Center, Omaha, NE

Peroxisome proliferator-activated receptor gamma (PPARγ) is a transcription factor expressed in quiescent hepatic stellate cells (HSC). With conversion to the activated HSC phenotype, PPARγ expression is markedly reduced. Restoration of PPARγ expression or activity results in a reversal of many of the profibrotic properties of HSC. The polypeptide hormone relaxin has antifibrotic effects on HSC, and through activation of its receptor RXFP1 induces elevated levels of cAMP. Because inducers of the cAMP/Protein kinase-A pathway have been implicated in the activation of PPARγ in other fibroblastic cells, we sought to determine the effect of relaxin treatment on PPARγ expression and activity in HSC. Primary rat HSC were culture-activated for 12 days before treatment with relaxin or a PPARγ agonist. As determined by Western blotting, PPARγ protein was present at a low level in untreated HSC. Relaxin caused a dose-dependent increase in the PPARγ protein level. To determine the effect of relaxin on PPARγ gene expression, HSC were treated with relaxin (1 nM), the PPARγ activator troglitazone (1 μM), or both, for 24 hours. Total RNA was then extracted from the cells, and expression of PPARγ was determined by real-time TaqMan RT-PCR. The expression level was normalized to that of 18S ribosomal RNA in the same samples. Troglitazone treatment resulted in a 60% increase in the expression of PPARγ, while relaxin had a more modest effect (43% increase in PPARγ expression). The combination of troglitazone and relaxin induced a 135% increase (p<.01 by ANOVA) in PPARγ expression, an effect greater than the additive effect of each agent alone. Finally, to examine the effect of relaxin and troglitazone on a fibrotic property of HSC, the cells were treated as above for 48 hours, and expression of α2(I) procollagen was determined by real-time RT-PCR. Troglitazone decreased in procollagen expression 65%, while relaxin alone had a lesser effect (55% decrease). The combination of relaxin and troglitazone was more effective than either treatment alone (75% decrease).

In summary, relaxin treatment of HSC increased PPARγ gene expression and protein levels. The combined action of relaxin and troglitazone on the expression of PPARγ and procollagen was greater than either agent alone. These data suggest that relaxin treatment may sensitize HSC to PPARγ agonist treatment by increasing the amount of cellular PPARγ. Through this mechanism, relaxin might be used to enhance the antifibrotic effects of these drugs and improve the treatment of hepatic fibrosis.

1419 HSC EXPRESS NALP3 AND ASC, AND UNDERGO DIFFERENTIATION IN RESPONSE TO URIC ACID CRYSTALS
Azuma Watanabe1, Aradeshir Hashmi1, Muhammad N. Jhandier1, Zeeshan Khan1, Fayyaz Sutterwala2, Muhammad A. Sohail1, Shamail Mahmoud1, Richard A. Flavel1, Wajahat Z. Mehal1; 1digestive disease, Yale University, New Haven, CT; 2Immunobiology, Yale University, New Haven, CT

Background: Hepatocyte apoptosis is known to induce hepatic stellate cell (HSC) differentiation but the signals mediating this are not known. Uric acid is produced during hepatocyte apoptosis, and has been identified as an important differentiation signal for dendritic cells and macrophages via the NALP3 pattern recognition receptor and the adapter molecule ASC. We hypothesized that uric acid also communicates hepatocyte apoptosis by inducing differentiation of HSC. Methods: RTPCR was performed using cDNA from primary murine HSC with primers for NALP3 and the adaptor protein ASC. Uric acid crystals (100 μg/ml) were added to LX-2 cells, and HSC from wild-type and ASC KO mice. 24 hours later cells were stained with α-smooth muscle actin and visualized by confocal microscopy, and cDNA was prepared for quantification of TGF-β and collagen1 mRNA expression by real-time PCR. LX-2 cells were cultured with or without uric acid crystals for 24 hours in a trans-well assay with PDGF as the chemo-attractant. We also examined inhibition of calcium signaling in LX-2 cells treated with or without uric acid crystals using by caged IP3. Finally, we confirmed the role of ASC in in-vivo liver fibrosis by the injection of carbon tetrachloride (CCL4) (850 μg/kg) in wild-type and ASC KO mice for 8 weeks. Liver tissue was stained with Sirius Red. Results: NALP3 and ASC KO mice were treated with Sirius Red Stain- ing, and up-regulated TGF-β and procollagen1 mRNA in HSC from wild-type but not ASC KO mice. Uric acid crystals inhibited the release of calcium via IP3 in LX-2 cells, and also inhibited PDGF induced chemotaxis. ASC KO mice injected with CCL4 had less fibrosis than wild-type mice on Sirius Red Staining. Conclusion: Uric acid inhibits HSC chemotaxis, induces actin reorganization and HSC differentiation via NALP3 and ASC.

L-TYROXINE (T4) INDUCES PROLIFERATION OF HEPATIC STELLATE CELLS VIA CELL SURFACE INTEGRIN \( \alpha V \beta 3 \) AND ENHANCES EXPRESSION OF \( \alpha \)-SMOOTH MUSCLE ACTIN AND COLLAGEN I TRANSCRIPTION
Isabel Zvibel\(^1\), Ella Barlev\(^1\), Adam Phillips\(^2\), Dikla Atias\(^1\), Shirley Abramovitch\(^1\), Zamir Halpern\(^1\), Ran Oren\(^1\);
\(^1\)Internal medicine, \(^2\)Gastroenterology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; 2Internal medicine, Assaf Harofeh Hospital, Tzrifin, Israel

Background/aims: We have previously shown that hypothyroidism is beneficial both for preventing and for treating liver fibrosis in animal models, while hyperthyroidism enhanced liver fibrosis. The aim of these studies was to determine the effect of thyroid hormone L-Tyroxine (T4) on the proliferation and activation of hepatic stellate cells via its newly described cell surface receptor, integrin \( \alpha V \beta 3 \) and to determine regulation of integrin \( \alpha V \) by T4 and extracellular matrix in hepatic stellate cells.

Methods: We have used primary rat hepatic stellate cells and the human hepatic stellate cell line LX-2. Total expression of integrin \( \alpha V \), \( \alpha \)-smooth muscle actin (\( \alpha \)-SMA) and signal transduction was assessed by Western blot analysis and cell surface integrin \( \alpha V \beta 3 \) expression was measured by fluorescence activated cell sorter. Proliferation was measured by cell counting and by a cell proliferation kit. Collagen I \( \alpha 1 \) and \( \alpha 2 \) promoter activity was assessed by transient transfection. Results: Expression of integrin \( \alpha V \) was low in quiescent cells and increased as cells became activated and trans-differentiated into myofibroblasts. LX-2 cells expressed \( \alpha V \beta 3 \) integrin and expression of this integrin was up-regulated by fibronectin, vitronectin and also by T4. T4, but not triiodothyronine, was a mitogen for primary hepatic stellate cells and for LX-2 cells. Proliferation of LX-2 cells was also enhanced when the cells were plated on fibronectin and vitronectin, ligands of \( \alpha V \beta 3 \). T4 induced nuclear translocation of phosphorylated erk1/erk2 and STAT3 in LX-2 cells. This effect was mediated via \( \alpha V \beta 3 \) integrin and was abolished in the presence of RGD peptide and tetrac, which compete with \( \alpha V \beta 3 \) cell surface receptor, integrin \( \alpha V \beta 3 \). Primary hepatic stellate cells cultured in thyroid hormone-depleted serum expressed very low levels of \( \alpha \)-SMA after 14 days in culture, but culturing the cells in the presence of 10-7M T4 resulted in strong expression of \( \alpha \)-SMA. Lastly, we have found that T4 enhanced transcription of collagen I \( \alpha 1 \) and \( \alpha 2 \) promoters in primary hepatic stellate cells both after 7 days and after 14 days in culture. Conclusion: We have shown that T4 is a mitogen for hepatic stellate cells via cell surface integrin \( \alpha V \beta 3 \), and is pro-fibrogenic by inducing \( \alpha \)-SMA expression and transcription of collagen I. These results suggest for the first time the mechanism responsible for the deleterious effect of hyperthyroidism on liver fibrosis in vivo.

GLUTATHIONE, BUT NOT CATALASE, IS IMPORTANT IN THE PROTECTION OF HEPATIC STELLATE CELLS AGAINST OXIDATIVE STRESS
Sandra Dunning, Rebekka Hannivoort, Laura Conde de la Rosa, Manon Buist-Homan, Klaas Nico Faber, Han Moshage; Division of Gastroenterology and Hepatology, University Medical Centre Groningen, Groningen, Netherlands

Background: We have previously shown that activated HSCs are sensitive to both superoxide anion and hydrogen peroxide induced cell death. HSC have different mechanism to detoxify oxidative stress such as peroxisomal catalase, superoxide dismutases and anti-oxidants like glutathione. Aim: 1) to evaluate the importance of catalase and glutathione in the protection against oxidative stress-induced cell death. 2) to evaluate the effect of oxidative stress on mRNA levels of antioxidant enzymes and activation markers of HSCs.

Methods: Primary rat hepatocytes and serum-starved culture-activated rat HSCs were exposed to oxidative stress induced by menadione (5-50\( \mu \)M), superoxide anion donor or hydrogen peroxide (0.2-5mM). Apoptosis and necrosis were determined by Acridine Orange and Sytox Green nuclear staining, respectively. mRNA expression of genes was determined by quantitative RT-PCR. Catalase was inhibited using 3-aminoatrazole (20mM). Glutathione levels were depleted by treatment with buthionine sulfoximine (BSO) at 200\( \mu \)M. Results: Menadione dose-dependently induced apoptotic but not necrotic death of HSCs. Glutathione depletion did not modulate menadione-induced cell death. Hydrogen peroxide did not induce cell death at concentrations up to 1mM hydrogen peroxide, but induced >90% necrosis at concentrations of 5mM. However, glutathione depletion dramatically increased the sensitivity of HSCs to hydrogen peroxide, resulting in >80% necrosis at 1mM hydrogen peroxide. Blocking catalase did not sensitize HSCs to hydrogen peroxide induced necrosis. In contrast, blocking catalase increased sensitivity of hepatocytes to hydrogen peroxide induced necrosis. In accordance, the relative expression of catalase mRNA was 13-fold higher in hepatocytes compared to HSCs. Menadione and hydrogen peroxide both induced the oxidative stress responsive gene HO-1 and this induction was further increased by GSH-depletion. The mRNA levels of the anti-oxidant enzymes catalase, Mn-SOD, Cu/Zn SOD and the activation markers TGF-\( \beta \), \( \alpha \)-SMA and collagen type 1 mRNA expression were not substantially altered by oxidative stress. Conclusion: In contrast to hepatocytes, catalase is not important in the protection of HSCs against hydrogen peroxide toxicity. Depletion of glutathione increases oxidative stress in activated HSCs as demonstrated by further induction of HO-1 and increases the sensitivity of activated HSC to hydrogen peroxide induced necrosis. Our results indicate that other hydrogen peroxide detoxifying enzymes, e.g. GSH-peroxidase, are important in HSCs. Targeting these enzymes may be a strategy to deplete activated HSCs as anti-fibrotic therapy, without affecting hepatocytes.

THE ADENINE RECEPTOR IS PRESENT IN RAT HEPATIC STELLATE CELLS (HSC), INDUCES HSC DIFFERENTIATION AND INHIBITS HSC CHEMOTAXIS
Azuma Watanabe, Ardeshir Hashmi, Muhammad N. Jhander, Samir Gautam, Muhammad A. Sohail, Shaima Mahmood, Zeeshan Khan, Wajahat Z. Mehal; digestive disease, Yale University, New Haven, CT

Background: Adenine was recently identified as the endogenous ligand of an orphan rat G protein-coupled, but the function of the adenine receptor is poorly characterized. We hypothesized that adenine, a uric acid pathway metabolite downstream of adenosine, promotes HSC differentiation. Methods: RTPCR was performed for adenine receptor expression in primary rats HSCs. Primary rats HSC were cultured with and without adenine (500\( \mu \)M). Twenty-four hours later, cDNA was prepared for quantification of collagen1 and TGF-\( \beta \) mRNA using Real Time RT-PCR. HSCs were also stained for \( \alpha \)-smooth muscle actin to visualize actin reorganization. To test if adenine inhibits HSC chemotaxis LX2 cells and rats HSCs were cultured with or without adenine (500\( \mu \)M) for 24 hours in a transwell
and integrin αV subunit co-localized on the membrane of primary rats HSCs. In LX-2 cells and primary rats HSCs, adenine induces actin reorganization. Adenine also up-regulates collagen 1 mRNA in rats HSCs, and inhibits chemotaxis in LX-2 cells and rats HSCs. Adenine also inhibits IP3 mediated increase in cytosolic Ca2+. Conclusions: Adenine receptor is present in primary rats HSCs. Adenine induces morphological change, and up-regulates collagen 1 mRNA in HSCs. Adenine inhibits chemotaxis and cytosolic calcium signaling in HSCs.

**Adenine increase collagen1 mRNA in Rats HSCs (P < 0.01).**

OSTEOPONTIN, AN OXIDANT STRESS-SENSOR IN HEPATOCYTES AND KUPFFER CELLS, TRIGGERS A FIBROGENIC RESPONSE IN STELLATE CELLS

Raquel Urtasun, Natalia Nieto; Medicine/Liver Diseases, Mount Sinai School of Medicine, New York, NY

Background: Activation of hepatic stellate cells (HSC) is the most critical feature in the pathogenesis of liver fibrosis and it appears to be mediated, among others, by factors released from hepatocytes and from Kupffer cells (KC). We have previously shown an essential role for hepatocyte- and KC-derived reactive oxygen species (ROS) on HSC activation and collagen I deposition. Microarray analysis identified osteopontin (OPN), an extracellular glycoprotein and a cell adhesion molecule implicated in tissue remodeling, as an ROS-sensitive protein. The Aim of this work was to address whether OPN, secreted by both hepatocytes and KC, could modulate the fibrogenic response in HSC. Results: Experiments were first carried out with either hepatocytes or with a HepG2 cell line overexpressing cytomechrome P450 2E1 (CYP2E1) to generate a state of oxidant stress. CYP2E1-expressing cells showed a 5-fold induction of OPN when compared to control cells. Arachidonic acid, a representative polyunsaturated fatty acid, further increased OPN levels 2-fold. These effects were prevented by addition of vitamin E, which blocks lipid peroxidation, and by diallylsulfide and diethyldithiocarbamate, CYP2E1 inhibitors. L-buthionine sulfoxime, a GSH-depleting agent, increased OPN mRNA levels by 2-fold. Similar results were found in primary hepatocytes from chronic ethanol-fed rats (with high CYP2E1) when compared to control hepatocytes. Likewise, KC isolated from chronic ethanol-fed rats (KCchal) displayed a 6-fold increase in OPN protein and mRNA when compared to controls. To understand the potential pro-fibrogenic actions of OPN, primary HSC were incubated with recombinant OPN (1-20nM) at different time points (6-48h). A significant increase in the expression of both intra- and extracellular collagen type I as well as α-smooth muscle actin (α-SMA) was observed at 24h post-treatment. Moreover, collagen type I up-regulation was accompanied by a decrease in matrix metalloproteinase 13 (MMP13), the MMP that specifically degrades collagen I. In contrast, MMP2 and MMP9 activities remained similar to those of non-treated cells. HSCcontrol and HSCethanol incubated with 1nM recombinant OPN showed a time-dependent increase in collagen I protein which was more
apparent in HSC_{ethanol}. Co-culture of HSC_{ethanol} with KC_{optical} or KC_{ethanol} also promoted HSC proliferation. OPN was found only in the extracellular medium of the ethanol co-culture. Conclusion: these results unveil that ROS trigger an increase in OPN which behaves as a profibrogenic factor playing a major role in extracellular matrix remodeling.

UPREGULATION OF SMOOTH MUSCLE MARKER GENES IN ACTIVATED HEPATIC STELLATE CELLS IS MEDIATED BY TRANSFORMING GROWTH FACTOR-β INDUCED EXPRESSION OF SERUM RESPONSE FACTOR

Jens Herrmann, Ute Haas, Axel M. Gressner, Ralf Weiskirchen;
Inst. of Clinical Chemistry and Pathobiocchemistry - Central Laboratory, RWTH University Hospital, Aachen, Germany

Background: Hepatic stellate cells (HSC) are prominent cellular effectors of liver fibrosis, which become activated during liver injury and transdifferentiate from quiescent, fat storing cells into a proliferative myofibroblast-like cell type (MBF). A common feature of activated HSC is upregulation of genes encoding known markers of smooth muscle cells (SMC) like α-smooth muscle actin (α-SMA) or SM22α. In SMC these genes are regulated by the serum response factor (SRF) in cooperation with specific co-factors. Aims: The aim of this study was to investigate the expression profiles of SRF and important co-factors in activated HSC and its role in the upregulation of SMC marker genes. Material/Methods: Primary rat HSC were culture-activated by seeding onto plastic surfaces and lysed at different days of cultivation. The expression levels of SRF, myocardin, and MRTF-A were detected by Western blotting and immunofluorescent cytochemistry. Transcriptional activity of SRF was examined by EMSAs. Results: During HSC transdifferentiation the SRF content increased in parallel to its known target genes α-SMA or SM22α associated with a nuclear accumulation and an enhanced DNA binding capacity of SRF in activated HSC. We also found an upregulation of the SRF co-factors myocardin and MRTF-A. Inhibition of SRF activity by specific siRNA or the Rho kinase inhibitor Y27632 resulted in decreased expression of SMC marker genes. SRF expression in HSC is depending on transforming growth factor-β (TGF-β) as demonstrated by direct induction or by inhibition of TGF-β signalling via a soluble TGF-β type II receptor or the ALK5 inhibitor SB431542 resulting in a decrease of SRF contents in activated HSC. Conclusions: We could demonstrate that SRF as well as its important SMC marker gene-specific co-factors myocardin and MRTF-A are upregulated during HSC activation and that SRF is functionally active. As TGF-β is a key effector in HSC activation and transdifferentiation, it is important that this cytokine also mediates SRF expression in these cells resulting in the well known upregulation of α-SMA and other SMC marker genes during this relevant process of liver fibrogenesis. To date it is still unknown which factors are involved in TGF-β induced upregulation of proteins that are important for cytoskeletal reorganization in activated HSC. We could show that the transcription factor SRF, which is known to be essential for SMC marker gene expression, is also a potent mediator of TGF-β signals during HSC transdifferentiation. Our findings suggest that SMC marker gene expression is similarly regulated in SMC and activated HSC, thereby representing their high plasticity.

HBV INFECT HEPATIC STELLATE CELLS AND AFFECT THEIR PROLIFERATION AND EXPRESSION OF EXTRACELLULAR MATRIX

Yan Cui, Yu Wang, Jidong Jia; liver research center, beijing friendship hospital, Capital Medical University., Beijing, China

BACKGROUND AND AIMS: The activation of hepatic stellate cell (HSC) plays an important role in liver fibrosis. But the exact mechanism of fibrogenesis induced by chronic hepatitis B has not been fully understood till now. The aim of this study was to observe whether HBV can infect HSC and its effect on proliferation of HSC and expression of extracellular matrix (ECM) in vitro. MATERIALS AND METHODS: Firstly, LX-2 cells (human activated HSC cell line) were incubated with the supernatant of HepG2.2.15 cells with the MOI 0.1-10 HBVDNA copies/cell and harvested after 24, 48 and 72 hours. HBV particles in LX-2 cells were observed by Electron microscopy (EM) and immunogold EM. HBVDNA and cccDNA were evaluated by real-time polymerase chain reaction (PCR). HBV replicative intermediates and HBV mRNA were detected by Southern blot/Northern blot and Dot blot. Secondly, various concentrations of HBVDNA, HBsAg or HBeAg were added into LX-2 cell culture for 48 hours. Cells survival was tested by MTT assay. And then, flow cytometric analysis was used to evaluate proliferation of HSC. Finally, the mRNA level of Collagen-I, Collagen-III were quantified by real-time polymerase chain reaction; and their protein levels were measured by enzyme-linked immunosorbent assay (ELISA). RESULTS: Some viral-like particles, diameter from 20 to 40nm, were found in endocytic vesicles but not in the cytoplasm in some of LX-2 cells. In these LX-2 cells, HBVDNA level was less than 0.05 copies /cell without finding of the replicative intermediates. However, HBVDNA, HBsAg and HBeAg can increase the cell cycle's [S+G2M]% and S% (P<0.05). Compare to control group, the mRNA level of collagen-I was significant increased by HBV(0.658±0.108 vs. 0.513±0.063, P<0.01) and HBeAg (0.689±0.182 vs. 0.45±0.078, 0.05); collagen-III mRNA level was increased by HBV(0.196±0.016 vs. 0.121±0.035, P<0.05) and HBeAg (0.171±0.019 vs. 0.118±0.082, P<0.05). HBV and HBeAg can also significantly increase the collagen-I protein expression (P<0.05). CONCLUSIONS: HBV might enter LX-2 cells through cytaphagy in vitro. No evidence supports HBV can replicate and express antigens in LX-2 cells. HBV and HBeAg have the effect of both promoting the proliferation of HSC and increasing the synthesis of major ECM.

REACTIVE NITROGEN SPECIES MODULATE EARLY EXTRACELLULAR MATRIX REMODELING VIA INDUCTION OF MATRIX METALLOPROTEINASE-1 AND TUMOR NECROSIS FACTOR α

Natalia Nieto, Francisco J. Cubero, Maria Vera, Raquel Urtasun; Medicine/Liver Diseases, Mount Sinai School of Medicine, New York, NY

To investigate whether reactive nitrogen species such as peroxynitrite (ONOO−) modulate the fibrogenic response and extracellular matrix remodeling, hepatic stellate cells (HSC) were incubated in the presence of either pure ONOO− or 3-morpholininosydnonimine (SIN-1), a ONOO− donor. Loss of cell viability, apoptosis, and cell proliferation did not occur as assessed by the MTT assay, Annexin V/propidium iodide staining, and methyl[3H]Thymidine incorporation, respectively.

Disclosures:
The following people have nothing to disclose: Natalia Nieto, Francisco J. Cubero, Maria Vera, Raquel Urtasun.
Nuclear in vitro transcription run-on assays, Northern blot analysis, and quantitative RT-PCR indicated similar COL1A1 and COL1A2 mRNA expression under both treatments, suggesting a likely post-translational regulation of collagen I expression. There was a dose-dependent decline in intra- and extracellular collagen I protein along with an increase in matrix metalloproteinase 1 (MMP1), the metalloproteinase that specifically degrades fibrillar collagen I, and in tumor necrosis factor α (TNFα), which were blocked by the ONOO- scavengers glutathione ethyl ester (GSH-EE), uric acid, and ebselen. Tissue inhibitor of metalloproteinase 1 (TIMP1) protein expression remained similar to that of non-treated HSC, and α-smooth muscle cell actin expression suggested decreased HSC activation. ONOO- triggered nitration of MMP1 and MMP13 likely promoting collagenolytic activity as shown by the lower active molecular weight bands, and it also led to transactivation of the MMP1, MMP13, and TNFα promoters. A TNFα neutralizing antibody and GSH-EE, a permeable and soluble form of GSH, blocked the transactivation of the MMP1 promoter, while treatment with L-buthionine sulfoximine, which depletes GSH stores, or with TNFα further transactivated the MMP1 promoter. Incubation of HSC with TGFβ after SIN-1 or ONOO- pre-treatment, did not lead to a pro-fibrogenic response. Similar results were obtained in rats injected with CCl4 and co-treated with SIN-1, validating a protective role for ONOO in the early fibrogenic response. However, highly activated HSC and HSC from chronic alcohol-fed rats with higher levels of GSH, an efficient ONOO- scavenger, were insensitive to the antifibrogenic actions of ONOO- due to overproduction of TGFβ and of ROS rather than of TNFα, as well as to high GSH levels, a powerful ONOO- chelating agent. The data suggest that although protective, the antifibrogenic actions of ONOO- are likely to occur only in the early stages of HSC activation.

1428 THY-1 DISTINGUISHES BETWEEN HEPATIC STELLATE CELLS AND LIVER MYOFIBROBLASTS IN VITRO AND IN VIVO
Jozsef Dudas, Tuemen Mansuroglu, Danko Batusic, Federico Moriconi, Bernhard Saile, Giuliano Ramadori; Gastroenterology and Endocrinology, Georg-August-University, Goettingen, Germany

Background/Aims: Several fibroblastic cell types have been described in the liver. So far, there is no reliable way to distinguish between activated hepatic stellate cells (HSC) and liver myofibroblasts in vivo. Thy-1, a recently described membrane-anchored myofibroblast marker was tested as a candidate for this function. Methods: The expression of Thy-1 was studied at mRNA and protein levels in vivo: in normal rat liver, in CCl4-induced acute and chronic rat liver injury, in partial hepatectomy (PH)-induced rat liver regeneration and in the rat liver regeneration model of 2-acetylaminofluorene treatment and PH (AAF/PH), in vitro: in isolated rat liver cells. Results: Thy-1+ cells were detected in the periportal area of rat liver specimens in normal-, injured- and regenerative-conditions. In chronic liver injury weak Thy-1+ reaction was found in the sinusoids of the parenchyma. Portal and septal myofibroblasts were Thy-1+ cells. In liver regeneration Thy-1, smooth-muscle alpha-actin (SMA) and desmin were located mainly in the portal area, but all of them showed perisinusoidal reaction as well. While desmin and SMA were relative homogenously distributed in the sinusoids, Thy-1 was only present in the sinusoids adjacent to the portal tract. The pericentral sinusoids were Thy-1+. SMA in the pericentral sinusoids also co-localised with Fas-ligand (Fasl).

Comparative immunohistochemical analysis revealed a co-localisation of Thy-1 and SMA, but not of Thy-1 and cytokertatin-19 or Thy-1 and alpha-fetoprotein in the AAF/PH model. Investigation of isolated rat liver cell populations confirmed that liver myofibroblasts are Thy-1-positive cells, while hepatocytes, HSC and liver macrophages are not, moreover, Thy-1 was not inducible by several cytokines in HSC. Conclusion: Thy-1 is the first cell surface marker to identify liver myofibroblasts in vivo and in vitro, and is not expressed in "oval cells".

1429 T3 ENHANCES EXPRESSION OF α-SMOOTH MUSCLE ACTIN AND OF CYTOKINES TNFα AND SDF1α IN PRIMARY STELLATE CELLS, YET INHIBITS COLLAGEN I TRANSCRIPTION
Isabel Zvibel1, Dikla Atias1, Adam Phillips2, Shirley Abramovitch1, Zaki Kraiem1, Zamir Halpern1, Ron Oren1; 1Gastroenterology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; 2Internal medicine A, Assaf Harofeh Hospital, Zerifin, Israel

Background/Aims: We have previously shown that hyperthyroidism caused more rapid appearance of liver fibrosis in a thioacetamide rat model of liver fibrosis. The purpose of the present studies was to determine whether expression of thyroid hormone receptors changes in quiescent and activated primary hepatic stellate cells and hepatic stellate cells that trans-differentiated into myofibroblasts. Moreover, we have investigated the effect of T3 on proliferation and activation of primary hepatic stellate cells, determined by expression of α-smooth muscle actin, various cytokines and activity of collagen I α1 and α2 promoters. Methods: Primary hepatic stellate cells were isolated from rat livers by pronase/collagenase digestion and Nycodenz gradient. Expression of thyroid hormone receptor α1 (TRα1), PDGF receptors and α-smooth muscle actin (α-SMA) was determined by Western blot analysis. Expression of cytokines MCP-1, TGFβ1, TIMP1 and 2, TNFα, SDF1α was determined by RT-PCR. Activity of collagen I α1 and α2 promoters was assayed by transient transfection. Results: Expression of TRα1 dramatically decreased as primary hepatic stellate cells progressed from quiescence to transdifferentiation into myofibroblasts, which was the opposite of the expression of PDGF receptors. T3 had no effect on the proliferation of activated hepatic stellate cells (7 days in culture) or of myofibroblasts (14 days in culture). Activated hepatic stellate cells grown in thyroid hormone-depleted serum showed low expression of TNFα and SDF1α, but in the presence of 10-7M T3, there was induction of expression of these two cytokines. Haptic stellate cells grown in thyroid hormone-depleted serum showed low α-SMA expression, but culturing the cells in this serum, supplemented with 10-7M T3, caused a two-fold induction of α-SMA expression. T3, in a dose responsive manner, inhibited transcription of collagen I α1 promoter in hepatic stellate cells after 7 days in culture, and less so in hepatic stellate cells after 14 days in culture, cells which have reduced expression of TRα1. Conclusion: The results suggest a pro-inflammatory effect of T3 and a role in activation of hepatic stellate cells. However, there is an anti-fibrogenic effect in early cultures of hepatic stellate cells, an effect which is less apparent in myofibroblasts, indicating that T3 may enhance appearance of liver fibrosis by increasing inflammation.

PRIMARY MOUSE HEPATIC STELLATE CELLS ARE LEPTIN AND ADIPONECTIN RESISTANT

Ben Schroyen, Inge Mannaeerts, Leo A. van Grunsven, Albert Geerts; Cell Biology (CYTO), Vrije Universiteit Brussel (VUB), Brussels, Belgium

Background & aims: Obesity is a well-known risk factor for the development of NAFLD. Therefore, we studied the relation between adipocytokines and the main fibrogenic effector cells of the liver: the stellate cells. We investigated the expression of leptin and adiponectin receptor isoforms, and studied the effects of both adipocytokines on quiescent and activated mouse hepatic stellate cells (mHSC). Methods: Activated stellate cells were obtained by culturing on polystyrene in the presence of 10% fetal bovine serum. The expression of the different receptor isoforms was examined by RTQ-PCR and Western blotting. Quiescent and activated mHSC cultures were exposed for different periods of time to leptin and adiponectin. Results: Leptin receptor isoform A (Ob-Ra) was expressed at the RNA level by both quiescent and activated mHSC. The long isoform Ob-Rb and short isoforms Ob-Rd and Re were only expressed by quiescent mHSC. Ob-Rc mRNA was not present. By Western blotting, we found 100 kDa immunoreactive protein, i.e. one or more of the short receptors. The 125 kDa variant (Ob-Rb) was absent. Long-term incubation with recombinant mouse leptin did not result in any morphological changes, neither in changes of α-SMA, GFAP, SREBP-1α/c and PAI-1 gene expression. We observed only marginal phosphorylation of ERK1/2, AKT and STAT3 following short-term incubation. Adiponectin receptor isoform 1 (Adipo-R1) mRNA was expressed by quiescent and activated mHSC at approximately the same level. Adipo-R2 mRNA was low in quiescent stellate cells and decreased further during activation. Using our own antibody to Adipo-R1, the 35 kDa naked receptor, as well as the posttranslationally modified receptor of 66 kDa was recognized in transfected HEC293T cells. In hepatocytes, we found an immunoreactive band of 55 kDa; in stellate cells a band of 72 kDa. At present, we examine whether these variations in molecular weight are due to glycosylation or other posttranslational modifications. By Western blotting with a commercially available antibody to mouse Adipo-R2, we detected a clear immunoreactive band (53 kDa) in hepatocytes. In contrast, we found no significant band in mHSC, irrespective of their stage of activation. Following incubation with recombinant globular mouse adiponectin, we found no changes in overall morphology of mHSC. Neither did we find measurable phosphorylation of AMPKα. Conclusions: Quiescent and activated mHSC carry the short leptin receptor(s) and a variant form of Adipo-R1. The nature of the posttranslational modification of Adipo-R1 is currently under investigation. Neither leptin, nor globular adiponectin have measurable effects on mHSC.

NOTCH SIGNALING IN NODULAR REGENERATIVE HYPERPLASIA AND HEPATIC MICROCIRCULATION

Mona Y. Ali1, Michael Dill1, Luigi Terracciano2, Markus H. Heim1, David Semela1; 1Division of Gastroenterology and Hepatology, University Hospital Basel, Basel, Switzerland; 2Institute of Pathology, University Hospital Basel, Basel, Switzerland

Background/Aims: Nodular regenerative hyperplasia (NRH) is a liver disease characterized by transformation of the liver parenchyma into small nodules with little to no fibrosis. The etiology of NRH is incompletely understood and probably related to vascular injury of the hepatic microcirculation. We have previously reported that knockout of Notch1 leads to NRH in mice (Croquefois et al. Hepatology 2005). The Notch signaling pathway is a signal transduction pathway which is essential for cellular proliferation, specification and differentiation. Notch signaling mediates intercellular communication through membrane-bound receptors. Notch1 regulates vascular development as well as angiogenesis and is expressed in liver sinusoidal endothelial cells. The aim of our study is to investigate the role of Notch1 in the pathogenesis of NRH. Methods: Isolated human primary liver sinusoidal endothelial cells (LSEC) were exposed to the Notch inhibitogamma-secretase inhibitor 1 (GSI, 0.1-10 uM). In vitro effects of Notch inhibition on LSEC were assessed by vascular tube formation on Matrigel, MTS proliferation assay and detection of apoptosis after nuclear staining with Hoechst 33342. In vivo proliferation rate of LSEC was assessed after BrdU incorporation on liver sections from control and conditional Notch1 knockout mice (inducible Notch1 disruption using an interferon-inducible Cre-recombinase transgene in combination with the loxP flanked Notch1 gene). Results: Inhibition of Notch signaling by GSI reduced vascular tube formation in vitro (100% DMSO vs. 32+/−31% at 1 uM GSI, n=3, p=0.018). GSI significantly inhibited proliferation in a dose-dependent manner and induced LSEC apoptosis (4.8+/−1.8% DMSO vs. 16.3+/−7.6% at 1 uM, n=4, p=0.025). Besides marked hepatocyte proliferation, Notch1 knockout mice with NRH (n=4) displayed increased BrdU incorporation in hepatic endothelial cells in comparison to controls (n=4) (54+/−13 vs. 19+/−14 positive endothelial cells/5 visual fields at 100x, p=0.011) in the absence of vascular thrombi. Conclusion: Pharmacological inhibition of Notch signaling inhibits vascular tube formation as well as proliferation and induces LSEC apoptosis in vitro. Knockout of Notch1 in mice leads to NRH and activation of hepatic angiogenesis. Further studies are ongoing to elucidate the molecular mechanisms in our model.

EFFECT OF ACUTE AND CHRONIC LIVER INJURY ON HEPATOTROPIC TARGETING PROPERTIES OF ERYTHROCYTE GHOSTS

Olav A. Gressner, Martin Koch, Birgit Lahme; Institute of Clinical Chemistry and Pathobiochemistry, University Hospital of the RWTH Aachen, Aachen, Germany

Background: Acute and chronic liver injury are accompanied by an enlargement of the macrophage pool due to proliferation of Kupffer cells (KC) and invasion of monocytes. Multiple mediators secreted by these cell types play a prominent role in the pathogenesis of liver diseases. Vesicular carriers, e.g. liposomes or erythrocyte ghosts (EG) with encapsulated appropriate drugs might be a promising tool to modulate their paracrine influ-
ences on pathogenetic reactions, such as cell damage and fibrogenesis, if efficient and highly specific uptake is guaranteed under disease conditions. Aim: Comparison of organotrophic, in particular KC targeting properties of xenogenic (human) and isogenic (rat) erythrocyte ghosts in rats with healthy, acutely and chronically damaged livers and evaluation of their utility in hepatotropic drug targeting. Methods: EG from humans and rats were prepared by controlled hemolysis with the hypotonic dilution technique of Wood at 0°C applying agarose A size exclusion column chromatography. Hemoglobin-free EG (residual haemoglobin < 1%, MCV average 61 fl) were loaded with model drugs for detection (FITC-dextran, 3H-inulin, 3H-doxorubicin), resuspended and injected intravenously into healthy, acute with thioacetamide (TAA) or D-galactosamine (GalN) injured livers and in TAA long-term treated (1-4 months) rats. Elimination kinetics from circulation, organ distribution and liver cell-specific uptakes were analyzed. For the latter purpose, hepatocytes, KC and other non-parenchymal liver cell types were isolated by collagenase digestion. Results: Healthy rats eliminated efficiently EG [t1/2 < 2 min], about 90% was found in the liver, selective uptake by KC. Only a minor fraction was localized in the spleen (liver/spleen ratio 15.4). The elimination rate decreased with the number of ghosts injected. In acute liver damage elimination rate decreased and correlated with the severity of injury [t1/2 < 14 min], about 30% was found in the liver with an increased fraction in spleen [liver/spleen ratio 6.4 (TAA) to 1.8 (GalN)]. Strongly reduced uptake by KC. If isolated KC from these livers were exposed with EG, a reduction of phagocytosis index by about 80% was measured. In chronic injury (1, 2, 4 months) leading to fibrosis (4 months) all the parameters of ghost elimination and uptake were similar to those in healthy rats. Conclusion: In acute damage KC targeting is hampered depending on the degree of injury. In chronic injury KC targeting is feasible with EG as a well tolerated isogenic vesicle carrier.

1433 ACTIVATION OF KUPFFER CELLS IS INVOLVED IN ALCOHOL-INDUCED DOWN-REGULATION OF HEPcidin EXPRESSION IN THE LIVER

Duygu Dee Harrison-Findik, Elizabeth Klein, John Evans, John L. Gollan; Internal Medicine, University of Nebraska Medical Center, Omaha, NE

Hepcidin plays a key role in iron homeostasis. We have demonstrated a role for alcohol in the regulation of iron metabolism, via down-regulation of liver hepcidin mRNA and up-regulation of duodenal iron transporter protein expression. This effect was abolished by antioxidant treatment. Moreover, a more prominent down-regulation of hepcidin expression was observed by alcohol in vivo than in vitro in alcohol-metabolizing HepG2 cells. These findings suggest that the non-parenchymal cells of the liver may play a role in alcohol-mediated regulation of hepcidin expression. Kupffer cells play an important role in alcholic liver injury. Of note, hepcidin is also regulated by inflammatory signals. However, the role of Kupffer cells in inflammation-mediated regulation of hepcidin expression is controversial. Furthermore, the role of Kupffer cells in alcohol-mediated regulation of hepcidin expression is unknown. The aim of this study was to investigate the role of Kupffer cells in the regulation of hepcidin expression by alcohol in vivo. For these studies, 129/Sv male mice were treated with gadolinium chloride (GdCl3), which is known to inactivate Kupffer cells. One day after the GdCl3 injection (IP, 400 µg/mouse), the mice were exposed to 20% ethanol in the drinking water for 7 days. The gadolinium injection was repeated on days 2 and 5 of alcohol treatment. Control mice were injected with 0.9 % NaCl. Mouse hepcidin 1 gene expression was determined by real-time quantitative PCR using Taqman fluorescent probes. As we have reported previously, mice exposed to ethanol displayed a significant decrease in liver hepcidin expression compared to mice fed with plain water. GdCl3 itself did not have an effect on hepcidin expression in the liver. However, the down-regulation of hepcidin expression was abolished in ethanol-treated mice injected with gadolinium chloride compared to mice injected with 0.9 % NaCl. Conclusions: Our findings suggest that Kupffer cell activation is required for the alcohol-mediated in vivo regulation of hepcidin expression in the liver. Both parenchymal and non-parenchymal cells may play a role in the regulation of iron metabolism by alcohol. These findings enhance our understanding of the mechanisms underlying hepatic injury in alcoholic liver disease.

Disclosures: The following people have nothing to disclose: Duygu Dee Harrison-Findik, Elizabeth Klein, John Evans, John L. Gollan

1434 DIFFERENTIAL MODULATION OF PRO- AND ANTI-REGENERATIVE CYTOKINES BY TLR STIMULATION IN NON-PARENCHYMAL LIVER CELLS

Agnes Szczeponek, Jan-Peter Sowa, Joerg F. Schlaak; Dept. of Gastroenterology and Hepatology, University Hospital of Essen, Essen, Germany

BACKGROUND: Recently, it has been suggested that the Toll-like receptor (TLR) system may play an important role in regulating liver regeneration after partial hepatectomy. To date, only little is known, however, how this effect is mediated and if the local innate immune system of the liver is involved. Therefore, we have studied the capacity of the most abundant innate immune cells of the liver, Kupffer cells (KC) and sinusoidal endothelial cells (LSEC), to produce mediators after TLR-stimulation that have pro- or anti-regenerative properties. METHODS: Isolation of murine KC was performed by counterflow elutriation while LSEC were isolated by anti-LSEC microbeads from C57BL6 mice. These freshly isolated KC and LSEC were stimulated by KC and LSEC. However, the pattern of pro- and anti-regenerative mediators varied significantly between the individual TLR ligands. Stimulation of TLR1, -2, -4, -7 and -8 induced pro-inflammatory (IL-6, TNF-α, HGF, IFN-α and IFN-β) cytokines on the transcriptional (quantitative RT-PCR) and protein level (ELISA). Supernatants from TLR-stimulated KCs and LSEC were used to stimulate freshly isolated hepatocytes. RESULTS: TLR1-9 agonists could induce the production of all mediators including HGF by KC and LSEC. However, the pattern of pro- and anti-regenerative mediators varied significantly between the individual TLR ligands. Stimulation of TLR1, -2, -4, -7 and -8 induced the expression of a pro-regenerative pattern (IL-6, TGF-α, HGF, TNF-α and anti-regenerative (IFN-α, IFN-β, TGF-β) cytokines on the transcriptional (quantitative RT-PCR) and protein level (ELISA). Supernatants from TLR-stimulated KCs and LSEC were used to stimulate freshly isolated hepatocytes. RESULTS: TLR1-9 agonists could induce the production of all mediators including HGF by KC and LSEC. However, the pattern of pro- and anti-regenerative mediators varied significantly between the individual TLR ligands. Stimulation of TLR1, -2, -4, -7 and -8 induced the expression of a pro-regenerative pattern (IL-6, TGF-α, HGF, TNF-α and IFN-β) in KC and LSEC, respectively. TLR3 ligands only were able to stimulate the production of IFN-α and IFN-β in both cell types. Stimulation of TLR5, -6 and -9 induced both pro- and anti-regenerative mediators. CONCLUSIONS: Our data show that the stimulation of non-parenchymal liver cells by TLR agonists leads to induction of mediators that are known to have pro- and anti-regenerative properties. Of note, this includes the production of HGF which was thought to be produced by stellate cells only. Therefore, the administration of TLR agonists with favourable ratios of pro- and anti-regenerative mediators before liver resection (e.g. TLR1, -2, -4, -7 and...
-8) may be used for optimizing liver regeneration postoperatively as has been previously shown for LPS (TLR4 agonist).

1435 CAUSAL KUPFFER CELL ACTIVATION BY FREE FATTY ACIDS SUPPRESSED THROUGH PEROXISOME PROLIFERATOR-ACTIVATED RECEPTORS (PPAR) δ

Noriyuki Obara, Koji Fukushima, Yoshiyuki Ueno, Yu Nakagome, Tooru Shimosegawa; Division of Gastroenterology, Tohoku University Graduate School of Medicine, Sendai, Japan

Backgrounds: Kupffer cells (KCs) play a central role in the development of non-alcoholic steatohepatitis (NASH). In terms of therapy, several options are under clinical trials, including ligands for PPAR as therapeutic agents. For establishment of the therapeutic basis, we postulated that there are mutual interactions among PPARδ, Toll-like receptor4 (TLR4) and saturated fatty acids (FA) regarding the activation of KCs. Materials and Methods: KCs isolated freshly from Balb-c mice were pre-incubated in a culture dish under the combination of or either of GW0742. PPARδ agonist, 9-cis retinoic acid (RA): retinoïd X receptor (RXR) agonist, resveratrol, 5-aminoimidazole-4-carboxamide-β-D-ribofuranoside (AICAR): AMPK activator, full length adiponectin (AD), C12, C14, C16, C18 saturated FA, cis- or trans-C18 FA for 24 hr in triplicate. After incubation with an additional supplement of S-form lipopolysaccharide (LPS) and LPS binding protein (LBP) as TLR4 ligands for 6hrs, the supernatant was measured for the measurement of concentration of TNFα and IL6 by enzyme-linked immunosorbent assay. Results: LPS activated KCs with a significant increase in the concentration of TNFα (100%; mean). GW0742 and RA suppressed the secretion of these cytokines slightly (97.5% and 94.9%, respectively). In contrast, combination of two agonists synergistically decreased the concentration of TNFα to 49.4%. AD, which alone reduced the TNFα concentration to 20.3%, did not enhance the suppression when in combination with GW0742 and RA (33.5%). C12, C14 and C16 saturated FA enhanced LPS/LBP inducible TNFα production in proportion to their carbon chain lengths (139.8%, 134.7% and 102.5%, respectively). Conversely, C18 FA suppressed it to 69.1%. PPARδ alone notably decreased TNFα production by the combination of FAs and LPS/LBP (C14: 94.9%, C16: 82.7%, C18: 53.1%), which was in contrast to the minimal suppressive effect of PPARδ ligand on TNFα secretion caused by LPS alone. IL6 secretion was affected by stimuli in the same manner as TNFα except that AD that increased the IL6 concentration to 119.5% and decreased the TNFα concentration to 20.3%. Trans-C18 FA alone, resveratrol and AICAR in combination with LPS did not appear to affect the cytokine production by KC. Conclusions: Activation of KCs was attenuated by PPARδ and RXR ligands, especially in combination. PPARδ alone suppressed the synergistic cytokine production by medium chain FA and LPS, but only minimally the part induced by LPS alone. These agonists and AD would be potent candidates as therapeutic options for NASH, along with ubiquitous expression of PPARδ and redundant free FAs in the circulation.

1436 VARIANT ERYTHROPOIETIC PROTOPORPHYRIA (EPP): A DISORDER WITH SEVERE EPP PHENOTYPE, NO MUTATIONS IN FERROCHELATASE DNA, AND ABNORMAL MITOFERRIN EXPRESSION.

Joseph R. Bloomer1, Yongming Wang1, George Shaw2, Nathaniel B. Langer2, Barry Paw1; 1Liver Center, University of Alabama at Birmingham, Birmingham, AL; 2Hematology, Brigham and Women’s Hospital, Harvard Medical School, Boston, MA

EPP is a genetic disorder in which excess production of protoporphyrin causes photosensitivity and in some cases liver disease that may necessitate transplantation. The enzyme defect is deficient activity of ferrochelatase (FECH), a mitochondrial enzyme that catalyzes insertion of Fe into protoporphyrin to form heme. Studies from this and other laboratories showed that most symptomatic patients have a mutation in one FECH allele that causes altered enzyme structure/function, along with a polymorphism (IVS3-48c) in the non-mutant FECH allele that lowers gene expression. However, we identified 8 individuals with EPP phenotype in 6 families, who have neither FECH mutations nor the polymorphism. The gender distribution, age range, and red cell protoporphyrin levels in the patients with variant EPP were similar to those in 32 symptomatic patients with usual EPP. All had photosensitivity; 5 (63%) had liver transplantation, compared to 31% in usual EPP. This suggests that genetic abnormalities outside the FECH locus can cause severe EPP, and led us to examine the possibility of abnormal mitoferrin (MFRN) expression. MFRN was recently shown by Paw and coworkers to be the major transporter for Fe in mitochondria for heme and Fe/S formation in vertebrate erythroblasts (Nature 2006: 440; 96-100), both of which could impact FECH activity since the enzyme contains a [2Fe-2S] cluster critical for activity. Specific RT-PCR amplification/sequencing of MFRN cDNA from RNA extracted from blood leukocytes in all 8 patients revealed both a normal and abnormal cDNA species. The abnormal species, which was not detected in a group of normal individuals or patients with usual EPP, had insertion of 477 bases of intron 2 between exon 2 and 3, causing a stop codon at triplet position 156 and resulting in a truncated protein. The abnormal species did not rescue anemia in zebrafish MFRN mutants, demonstrating loss of function in the transcript/protein. Studies using cultured lymphoblasts from 5 patients with variant EPP showed that formation of the abnormal MFRN mRNA was attended by a decrease in formation of normal MFRN mRNA as measured by quantitative real time PCR, when compared to 5 normal lymphoblast lines (1473±154 versus 2039±79 copies/ug total RNA, p=0.02). There was also a significant reduction in FECH activity in variant EPP lines (9.0±3.7 versus 22.1±3.2 v, p=0.01). Conclusions: A subpopulation with severe EPP has neither mutations nor the polymorphism IVS3-48c in FECH DNA, unlike patients with usual EPP. This is associated with abnormal expression of MFRN, the gene for the major transporter of Fe in vertebrate mitochondria.

DONOR HEPATOCYTES HAVE A SELECTIVE REPOLAPATION ADVANTAGE OVER HOST HEPATOCYTES IN ALPHA 1-ANTITRYPSIN DEFICIENCY

Govardhana Yannam1, Hesham Basma1, Tunda Hidvegi2, Kimiaki Tanaka1, Shintaro Sato1, Ron Wong3, David H. Perlmutter1, Ira J. Fox1; 1Department of Surgery, University of Nebraska Medical Center, Omaha, NE; 2University of Pittsburgh School of Medicine, Pittsburgh, PA; 3Stanford University School of Medicine, Palo Alto, CA

Introduction: Alpha-1-antitrypsin (AAT) deficiency is a common genetic disorder where the mutant AT-Z protein is retained in the endoplasmic reticulum of liver cells rather than secreted into the blood. In the liver, accumulation of the aggregated mutant protein produces cirrhosis and increases the risk of cancer by a gain-of-toxic function mechanism. In the lung, AAT deficiency results in premature development of pulmonary emphysema by a loss-of-function mechanism. Hepatocyte transplantation is a potentially effective therapy for liver based metabolic disorders, but expansion of donor cells appears to be necessary for maximum efficacy. In theory, increased apoptosis of native liver cells in patients with AAT should allow selective repopulation of the liver by donor hepatocytes following transplantation. We examined this issue in human AAT (hAAT) transgenic mice. Methods: hAAT transgenic mice (PiZ mouse model) were used as transplant recipients. Expression of the mutant human AAT protein in native liver cells generates liver cell injury that mimics that associated with AAT deficiency in man. Five-hundred thousand to one million hepatocytes derived from beta-galactosidase (ROSA26) transgenic mice were transplanted in the engraftment in the liver by intrasplenic injection. For some experiments, ROSA26 hepatocytes were transduced, at an MOI of 30, with a recombinant lentivirus expressing firefly luciferase. The efficiency of donor hepatocyte transduction was 30%. Engraftment and repopulation was assessed non-invasively by bioluminescence imaging, and, histologically, by lacZ staining. Results: After transplantation, the liver was progressively repopulated with donor hepatocytes, as assessed by non-invasive IVIS imaging, and two-to-three months after transplantation, approximately 20% of the native liver was replaced by ROSA26 hepatocytes, as determined, histologically, by lacZ staining. Conclusion: Hepatocyte transplantation should be effective therapy in patients with AAT deficiency that don’t have cirrhosis-induced liver failure, such as those with emphysema, because transplanted donor hepatocytes have a natural selective repopulation advantage over host hepatocytes following transplantation. Even with low transduction efficiency, non-invasive imaging is an important tool for cell transplantation that allows independent assessment of graft status, avoiding sampling error and the risks associated with biopsy.

Functional Loss of Transferrin Receptor 2 Decreases Basal Hepcidin Expression, But Does Not Abolish Regulation by Iron or Erythropoietin

Robert S. Britton1, Heather L. Morgan2, Mary C. Migas2, Gail M. Palmer1, Rosemary O’Neill1, William S. Sly2, Bruce R. Bacon1, Robert E. Fleming2,3; 1Division of GI and Hepatology, Saint Louis University School of Medicine, St Louis, MO; 2Pediatrics, Saint Louis University School of Medicine, St Louis, MO; 3Biochemistry and Molecular Biology, Saint Louis University School of Medicine, St Louis, MO

Hepcidin is a peptide hormone produced by the liver that negatively regulates dietary iron absorption and reticuloendothelial iron release. Hepcidin expression is downregulated by iron deficiency and erythropoietin, and is upregulated by inflammation. Loss of function mutations in transferrin receptor 2 (TfR2) lead to inappropriately low levels of hepcidin and iron overload, suggesting that hepatocellular TfR2 regulates hepcidin by sensing circulating iron. Aim: The aim of this study was to test the hypothesis that dietary iron or erythropoietin would effect changes in hepcidin expression in wild-type but not TfR2 mutant mice. Methods: Homozygous male TfR2 mutant (Y245X) mice and wild-type FVB mice were used. Some mice (n = 5-7) were placed on diets containing either 15, 250 or 25,000 ppm iron ad lib for 2 weeks after weaning. Additional mice (n = 5-6) were treated with erythropoietin (50 U/mouse/day s.c. for 3 days) or an equivalent volume of saline. After sacrifice, iron parameters (tissue iron concentration, transferrin saturation) were measured, and liver hepcidin mRNA expression was quantified by RNA blot analysis. Results: For each diet, hepatic iron concentrations were significantly higher and splenic iron concentrations were lower in TfR2 mutant mice compared with wild-type mice. Liver hepcidin mRNA expression was decreased by at least 75% in TfR2 mutant mice compared with wild-type mice at each level of dietary iron. However, both wild-type and TfR2 mutant mice demonstrated increased hepcidin expression in response to increased dietary iron (see Table). Treatment with erythropoietin stimulated erythropoiesis in both types of mice, as evidenced by an increase in hematocrit. Erythropoietin treatment of wild-type mice decreased hepcidin mRNA levels by 73%, and in TfR2 mutant mice, erythropoietin further suppressed the already low basal hepcidin mRNA levels. Conclusions: Loss of functional TfR2 results in a substantial decrease in basal expression of hepcidin mRNA in the liver. However, relative to basal expression, hepcidin remains responsive to changes in dietary iron levels and to erythropoietin, indicating that TfR2 is not essential for these responses.

HEPATOESPLENOMEGALY AND BLOOD PARAMETERS IN GAUCHER DISEASE - ANALYSIS OF DOSE-RESPONSE RELATIONSHIPS IN ENZYME REPLACEMENT THERAPY
Stephan vom Dahl1, Carla Hollak2, Ari Zimran3, Joel Charrow3, Katherine Kacena2, Pram Mistry2, Greg Grabowski2; 1Dept. of Internal Medicine, Gastroenterology and Hepatology, St. Franziskus-Hospital, Academic Teaching Hospital, University of Cologne, Cologne, Germany; 2Cincinnati Childrens Hospital, Cincinnati, OH; 3Childrens Memorial Hospital, Chicago, IL; 4Amsterdam Medical Center AMC, Amsterdam, Netherlands; 5Genzyme Corporation, Boston, MA; 6Yale School of Medicine, New Haven, CT; 7Shaare Zedek Medical Center, Jerusalem, Israel

Background: Gaucher disease is based on a deficiency of glucocerebrosidase and is the most frequent lysosomal storage disease, leading to hepatosplenomegaly, pancytopenia and bone destruction. Elevated transaminases are frequent, cirrhosis occurs and hepatocellular carcinoma without preexisting cirrhosis has been described. Aims: The purpose of the present study was to analyze if enzyme replacement therapy (ERT) with imiglucerase demonstrates dose-response relationships across disease parameters in patients with type 1 Gaucher disease (GD) within the range of doses used in routine clinical practice. Methods: The analysis included all patients with type 1 GD enrolled in the International Gaucher Registry (ICGG) diagnosed after 1991, who received ERT with imiglucerase and had an intact spleen. ERT dose was defined as the average dose over the first 3 years of treatment. Propensity score matching was used to control for differences in baseline disease severity between ERT dose groups categorized as 15U/kg (5 ≤ <29 U/kg/2 wks.), 30 U/kg (29 ≤ <48 U/kg/2 wks.), 60 U/kg (48 ≤ <75 U/kg/2 wks.). Liver and spleen volumes, hemoglobin and platelet count were assessed during follow-up (0-60 months) through non-linear mixed effects models. The rate (T50) and extent (Emax) of ERT treatment effect for each parameter analyzed: liver and spleen volumes, hemoglobin, platelet count were compared across groups. Results: Propensity score matching resulted in 3 comparable groups of 122 patients each. ERT with imiglucerase at 15, 30, 60 U/kg/2 wks., respectively. Statistically significant dose-response relationships were found across groups for each parameter analyzed: liver and spleen volumes, hemoglobin, platelet count, in regard to rate and extent of improvement over 60 months. Conclusions: ERT with imiglucerase results in statistically significant dose-dependent improvement in organomegaly and hematological parameters in patients with type 1 GD. Propensity score matching and non-linear mixed effects models can be used to assess outcomes based on observational data from an international rare disease registry.

DIVERGENT PATHOGENESIS FOR HEPATOCYSTIN AND SEC63P ASSOCIATED POLYCYSTIC LIVER DISEASE?
Esme Waanders1, Cathy N. Maass2, René H. te Morsche1, Erwin H. van Geffen3, Han J. van Krieken2, Joost P. Drenth1; 1Department of Gastroenterology and Hepatology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; 2Department of Pathology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; 3Department of Surgery, Jeroen Bosch Hospital, Den Bosch, Netherlands

Polycystic liver disease (PCLD) is an inherited disorder characterized by the presence of numerous hepatic cysts. Cysts are thought to arise from malformation of the ductal plate. PCLD is associated with mutations in PRKCSH or SEC63, encoding hepatocystin and Sec63p respectively, but expression patterns in diseased and normal liver are unknown. To gain insight in the pathogenesis of PCLD, we assessed the immunohistochemical expression of hepatocystin and Sec63p in fetal liver (n=17, range 11 weeks after gestation to 15 months of age), PCLD (n=21) and normal adult liver (n=13). Cytokeratin 18 and 19 staining was used to ascertain the biliary origin of cysts. In fetal tissue, there was intense expression of hepatocystin in ductal plate, bile ducts and hepatocytes. After 26 weeks of gestation the intensity dropped to levels seen in adult liver tissue. In contrast, Sec63p staining was weak in bile ducts throughout development but prominent in early hepatocytes. In adult PCLD tissue, hepatocystin was expressed in hepatocytes, bile ducts, and in cyst epithelium of PRKCSH mutation negative patients. In contrast the majority of cysts (90%) from PRKCSH mutation carriers did not express hepatocystin. We detected an on-off mechanism: hepatocystin expression was either absent or present in all cuboid cells lining the cyst. Sec63p expression was observed in all cyst epithelia regardless of mutational state. Bile duct origin of the cyst epithelia was confirmed by cytokeratin staining patterns.

In conclusion: Hepatocystin is probably required for the development of bile ducts in fetal liver, and is lost from cyst lining in the large majority of germline PRKCSH mutation carriers. This observation corroborated with the hypothesis that cyst formation in PCLD results from a cellular recessive mechanism involving loss of hepatocystin. In contrast, Sec63p was present in all samples, regardless of mutational status, suggesting that SEC63 associated PCLD occurs via another mechanism.

EX VIVO GENE THERAPY REVISITED: COMBINATION OF LENTIVIRUS-MEDIATED GENE TRANSFER AND PREPARATIVE IRRADIATION OF HOST LIVER RESULTED IN LONG-TERM AMELIORATION OF JAUNDICE IN A RAT MODEL OF CRIGLER-NAJJAR SYNDROME TYPE 1
Jinlan Jiang, Xia Wang, Laibin Liu, Yong Chen, Chandan Guha, Namita Roy-Chowdhury, Jayanta Roy-Chowdhury; Albert Einstein College of Medicine, Bronx, NY

Background and aim: Ex vivo gene therapy for inherited metabolic liver diseases offers the advantages of not requiring livers from live or deceased donors and not needing immunosuppression. However, heretofore, the benefits of ex vivo gene therapy for liver diseases have been minimal because of the relative inefficiency of retroviral vectors to transduce primary hepatocytes and the small number of phenotypically modified hepatocytes that can be transplanted in one sitting. In the present study, we have overcome these hurdles using highly effec-
tive third generation lentiviral vectors and preparative hepatic irradiation to induce preferential proliferation of the transplanted hepatocytes. Methods: Adult UGT1A1-deficient jaundiced Gunn rats (model of Crigler-Najjar syndrome type 1) underwent 66% hepatectomy followed by hepatic irradiation (50 Gy). Primary hepatocytes were isolated by collagenase perfusion of the resected lobes. The isolated cells were incubated with a lentiviral vector expressing human UGT1A1 from a hepatocyte-specific albumin promoter (MOI = 5) at 40°C for 4 hr. After plating an aliquot for subsequent determination of gene transfer efficiency, 106 hepatocytes were transplanted back into the Gunn rat by intrasplenic injection through a flank incision. The recipients were followed for serum bilirubin levels. Recipients were sacrificed at various intervals, up to 6 months, for evaluation of liver repopulation by phenotypically corrected cells by immunohistochemical staining of liver sections, western blot of liver homogenates and determination of hepatic UGT1A1 activity. Results: Transduction efficiency of the isolated primary hepatocytes was 20-30%. After transplantation, there was progressive repopulation of the liver by engrafted hepatocytes over 8-12 weeks, at which time point 8-12% of the hepatocytes stained positive for human UGT1A1. Western blot and hepatic UGT1A1 activity exhibited commensurate increase. Serum bilirubin levels declined by 50-70% in 8 weeks and remained at that level for the 6-month observation period. Liver histology and other liver functions tests remained normal, and there were no detectable serum antibodies against human UGT1A1. Conclusions: Efficient transduction of the primary hepatocytes and preferential proliferation of the transplanted hepatocytes resulting from preparative hepatic irradiation and partial hepatectomy led to successful long-term amelioration of jaundice. Although UGT1A1 is a foreign protein to Gunn rats, there was no immune response against the transgene product, probably because its expression was limited to hepatocytes.

PULSATILE, PRO-AUTOPHAGIC THERAPY WITH RAPAMYCIN REDUCES THE INTRAHEPATIC ACCUMULATION OF ALPHA-1-ANTITRYPSIN MUTANT Z PROTEIN AND REDUCES LIVER INJURY IN AN IN VIVO MODEL
Shalesh Kaushal1, Manni Annamali2, Jeffrey Teckman1,2; 1Pediatrics, St. Louis University, Saint Louis, MO; 2Biochemistry and Molecular Biology, Saint Louis University School of medicine, Saint Louis, MO; 3Ophthalmology, University of Florida, Gainsville, FL

Homozygous, PIZZ, alpha-1-antitrypsin (a1AT) deficiency occurs in 1 in 2,000 Americans, and can cause liver disease and hepatocellular carcinoma in children and adults. Studies in human tissue and model systems have shown that the a1AT mutant Z gene encodes a mutant protein which accumulates within hepatocytes leading to chronic hepatocellular death, and a low-grade hepatic regenerative response. Several proteolytic mechanisms are activated within hepatocytes to cope with the intracellular burden of the accumulated mutant protein, including autophagy. Autophagy is thought to be especially important in disposal of the unique polymerized conformation of the a1AT mutant Z protein, which forms insoluble intracellular aggregates and is thought to be especially injurious to the cell. Autophagy is a vacuolar system of intracellular disposal involved in the management of aggregated proteins, organelle recycling, cell stress, and differentiation, and which is known to be upregulated by the agent, rapamycin. Recent data from our laboratories indicates that rapamycin most efficiently upregulates autophagy in murine systems when given in weekly dose pulses, as compared to daily doses. This scheme causes a cyclical induction of autophagy through specific molecular binding mechanisms. Therefore, we evaluated the effect of rapamycin administration on PiZ mice, a well characterized model which recapitulates many features of human a1AT deficiency liver disease. As expected, daily dosing had no effect on autophagic activity, on the intracellular accumulation of a1AT mutant Z protein, or on the progression of liver injury, even when therapeutic blood levels were confirmed. Weekly dosing of rapamycin however, did increase autophagic activity, as shown by increased numbers of autophagic vacuoles and by quantitative LC3 immunoreactivity. The increased autophagy was also associated with a reduction in the intracellular accumulation of a1AT mutant Z protein in the polymerized conformation. Markers of hepatocellular injury, including cleavage of ER stress-related caspase 12, and lobular infiltration with inflammatory cells, were also decreased. This is the first report of a successful in vivo drug method for reduction of intracellular accumulation a1AT mutant Z protein and by reducing the progression of liver injury.

ALCOHOL CONSUMPTION FURTHER MODULATES HEPATIC HEPCIDIN GENE EXPRESSION IN AN ANIMAL MODEL OF HEMOCHROMATOSIS
Linda M. Fletcher1,2, Mandy L. Heritage2, Therese L. Murphy2, Claudia Popa2, Kim R. Bridle2,3, Gregory J. Anderson4,2, Darrell H. Crawford2,3; 1Gastroenterology and Hepatology, Princess Alexander Hospital, Brisbane, QLD, Australia; 2School of Medicine, University of Queensland, Brisbane, QLD, Australia; 3Gallipoli Research Foundation, University of Queensland, Brisbane, QLD, Australia; 4Population Studies and Human Genetics Division, The Queensland Institute of Medical Research, Brisbane, QLD, Australia

Background: Co-toxicity is an important factor in determining the pathogenesis of progressive liver disease. The mRNA expression of the hepatic iron sensor peptide hepcidin, is decreased in human subjects and in animal models of HFE-related hemochromatosis and also following chronic alcohol consumption. We aimed to determine i) whether the inhibition of hepcidin expression is an early event following alcohol consumption, ii) whether alcohol further suppresses the decreased hepcidin mRNA expression seen in Hfe-/- mice and iii) whether the co-toxic effect of alcohol and iron exacerbates liver injury.

Methods: Hfe-/- knockout and C57BL/6 (wild type; WT) mice were pair-fed an alcoholic liquid diet 8 weeks. A time course experiment (1-4 weeks alcohol feeding) was also conducted in WT mice to determine whether the effect of alcohol on hepcidin gene transcription was immediate, or effective only following long term alcohol exposure. mRNA expression of hepatic hepcidin, duodenal ferroportin and DMT-1 were measured by RT-PCR. Liver injury was estimated by histopathology, ALT and hepatic lipid peroxidation. Results: Hepcidin mRNA expression was significantly decreased (p<0.003), and duodenal ferroportin and DMT-1 expression were increased (p<0.0003, p<0.0001 respectively) in alcohol-fed WT mice (n=7) following 8 weeks of alcohol feeding. Consistent with the genetic detect,
haptocorrin mRNA was decreased [2.6 fold; p<0.0001] in Hfe-/ mice (n=9) fed the control diet compared to WT and this was further suppressed [3.6 fold; p<0.0001] in alcohol-fed Hfe-/ mice. The earliest time point at which alcohol significantly decreased haptocorrin expression was 4 weeks [p<0.036]. ALT was increased in all alcohol-fed mice at 8 weeks of feeding, but this only reached significance in Hfe-/ mice [p<0.03], implying the 5 fold increased hepatic iron in these animals may have compounded the liver injury, even though lipid peroxidation was not significantly increased. Conclusion: Hepcidin inhibition due to excess alcohol consumption occurs after 2 - 4 weeks of alcohol consumption. The fact that alcohol further suppresses haptocorrin mRNA expression in Hfe-/ mice, suggests that alcohol-specific pathways, independent of iron signalling, modulate hepcidin gene expression. The co-toxic effect of moderate iron overload and alcohol is present, but subtle, at 8 weeks of chronic alcohol consumption.

REVISITATION OF A COHORT OF 482 ITALIAN PATIENTS WITH HEREDITARY HEMOCROMATOSIS: CHANGES IN THE LAST THREE DECADES

Anna Ludovica Fracanzani1, Luca Valenti1, Alessandra Maraschi2, Mirella Fraquelli2, Sabina Coletti3, Alberto Piperno3, Dario Conte2, Silvia Fargion1; 1Department of Internal Medicine, Fondazione Policlinico IRCCS, University of Milan, MILANO, Italy; 2Division of gastroenterology II, Fondazione Policlinico IRCCS, University of Milan, MILANO, Italy; 3Department of Clinica Medica, A.O. S. Gerardo, Monza, University of Milan Bicocca, MILANO, Italy

Background: Significant improvement in diagnosis and management of hereditary hemochromatosis (HH) has occurred in the last years. Whether this has led to changes in severity of the disease at presentation and to a different importance of genetic and environmental factors has not been assessed. The aim of this study was to revisit our series of Italian patients with HH and compare their clinical and genetic characteristics along 3 consecutive decades of surveillance (1975-84 group A, 1985-94 group B, 1995-05 group C). Patients: A cohort of 482 (369 male, 112 female), outpatients with HH diagnosed according to standard criteria, prospectively followed for 367 months (range, 1-367) in three liver units. Methods: demographie, anthropometric, clinical, biochemical and virological data were collected at diagnosis, HFE gene mutations were detected in 433 patients, 317 underwent liver biopsy. All cirrhotic patients underwent a surveillance program for early detection of hepatocellular carcinoma (HCC) with ultrasonography every 6 months. Results: A significant lower prevalence of cirrhosis (75%; 57%, 28%, p<0.001), HCC (41%, 27%, 5%, p=0.0001), HBV infection [12%, 7%, 1.3% group A and B vs C p<0.03], HCV infection [26%, 16%, 3%, group A and B vs C p=0.001], alcohol intake [g/day] (56±65, 48±50, 23±32, p=0.001) and ALT levels [61±80, 76±117, 46±38 U/l, group A and B vs C p=0.01] was observed in the last decade. Patients in the three decades had similar prevalence of C282Y homozygosity (61%) and of transferrin saturation, and increased prevalence of compound heterozygosity during the 3 decades. Significant lower serum ferritin [ 2269±1388, 2174±2095, 1217±1171 ng/ml, group A and B vs C p<0.001], and iron removed to reach depletion [16±11, 10±6, 7±10 g, p=0.001] but significant higher total cholesterol [155±43, 163±53, 189±42, mg/dl, p=0.001], and BMI [23±2.3, 23±2.8, 24±2.9, Kg/m2, p 0.001] and lower fasting glucose [119±4.5, 104±33, 98±27mg/dl, p=0.01] were observed in the last decade. A significant decrease in the prevalence of diabetes, hypogonadism and cardiac alterations but not of arthropathy was observed. Conclusion Patients with HH diagnosed during the last 10 years have less severe liver disease likely for an improved medical attention to this disease and for a better prevention of environmental risk factors. The higher prevalence of metabolic alterations in patients diagnosed more recently reflects findings in general population and implies modification of HH clinical presentation.

UPREGULATION OF FERROPORTIN AND DMT1 EXPRESSION IN CIRRHOTIC HUMAN LIVERS: A LINK TO HEMOSIDEROSIS?

Ottar M. Bergmann1-2, M. Meleah Mathas2, Kimberly E. Broadhurst2, Jamie A. Weydert2, Neal Wilkinson4, James R. Howe4, Warren N. Schmidt1-2, Kyle Brown1-2; 1Division of Gastroenterology and Hepatology, Department of Internal Medicine, University of Iowa Hospitals and Clinics, Iowa City, IA; 2Internal medicine, Veterans Administration medical center, Iowa City, IA; 3Department of Pathology, University of Iowa Hospitals and Clinics, Iowa City, IA; 4Department of Surgery, University of Iowa Hospitals and Clinics, Iowa City, IA

Iron deposition unrelated to hereditary hemochromatosis (hemosiderosis) occurs commonly in cirrhotic livers and has been associated with more advanced disease and accelerated decompensation, but the pathophysiology of this condition is poorly understood. The aim of this study was to compare the expression of proteins involved in the regulation of iron metabolism in control and cirrhotic human livers to gain insight into the possible causes of hemosiderosis. Methods: Cirrhotic human livers (n=23) were collected at liver transplantation, donor livers (n=6) were obtained from a tissue bank, and normal liver tissue was obtained at the time of resection of liver tumors (n=5). Hepatic levels of mRNA for DMT1 (all isoforms), ferritin (H chain), ferroportin, hemosudulin, hepcidin, transferrin, transferrin receptor (TFRC) and transferrin receptor 2 (TFR2) were quantified by real-time PCR. Expression of DMT1 isoforms was assessed by semiquantitative RT-PCR. Western analysis was performed for ferroportin, DMT1, TRFC and ferritin. Hepatic iron concentrations (HIC) were measured using a spectrophotometric method. Results: Levels of ferroportin and DMT1 mRNA were significantly higher in cirrhotic livers than in normals (p=0.031 and 0.008, respectively). Levels of ferroportin and DMT1 transcripts were strongly correlated in cirrhotic livers (r=0.75; p<0.001), but neither correlated with hepcidin mRNA or with HIC. Both normal and cirrhotic livers expressed the 1B, 1E and non-IRE isoforms of DMT1, but the 1A isoform was detected in only a few cirrhotic livers; however, there was no relationship apparent between expression of the isoforms and HIC in the cirrhotic livers. Hepcidin transcripts were significantly higher in the donor livers than in the cirrhotics (p=0.003); nonetheless, hepcidin mRNA correlated significantly with HIC in the latter group (r=0.57; p=0.005) but not the former. No differences in mRNA levels for ferritin, hemosudulin, TFRC or TFR2 were seen. By Western blot, neither DMT1 nor ferroportin varied with HIC in the cirrhotic livers, while ferroportin was dramatically reduced in donor livers. In contrast, TRFC decreased while ferritin increased with increasing HIC in the cirrhotic livers. Conclusions: Despite apparently normal regulation of hep-
cidin expression, DMT1 and ferroportin are increased at both the level of mRNA and protein in cirrhotic liver. Similar findings have been reported in the duodenum of cirrhotics, suggesting these alterations may play a role in aberrant regulation of iron metabolism in cirrhosis. Donor livers show evidence of an acute phase response with elevated hepcidin mRNA and decreased ferroportin.

1446
13C-METHACETIN BREATHE TEST: A NEW TOOL TO PREDICT THE PRESENCE OF LIVER VASCULAR MALFORMATIONS IN PATIENTS WITH HEREDITARY HAEMORRHAGIC TELEANGIECTASIA

Marcello Candelli1, Maurizio Pompiili4, Giulia Bosco4, Patrizia Suppresse2, Giovanna Pasculli2, Gennaro Lenato2, Luigi Castorani3, Maurizio Memeo3, Anna Rita Sorbo4, Gian Ludovico Rapaccini4, Giovan Battista Gasbarrini4, Antonio Gasbarrini4, Carlo Sabbà2; 1Emergency department, Catholic University of Rome, Rome, Italy; 2Internal Medicine and Public Health, University of Bari, Bari, Italy; 3Radiology, University of Bari, Bari, Italy; 4Internal Medicine, Catholic University of Rome, Rome, Italy

Hereditary Hemorrhagic Teleangiectasia (HHT) is a systemic disease with arteriovenous malformations (AVMs) due to ENG or ALK1 gene mutations. The liver is involved in about 70% of patients; the diagnostic gold standard is multislice computed tomography (MSCT). Breath tests based on 13C-methacetin (MBT) and aminopyrine (ABT) have been used to explore liver functions; the former permits the evaluation of hepatic blood flow as this drug has a high hepatic extraction ratio altered by vascular shunts in the liver, while the latter is an indirect measurement of hepatocellular function. The aim of our study was to evaluate the effect of AVMs on results of MBT and ABT in HHT patients and the accuracy of MBT in depicting AVMs compared to MSCT. Methods: forty-five patients (22 males; mean age 52 ± 15 years) with HHT were enrolled along with 45 healthy controls (19 male; mean age 52 ± 15 years). Thirty patients with liver cirrhosis were excluded from the study. All subjects performed MSCT to evaluate HHT liver involvement. MBT (39 pts) and ABT (16 pts) were performed as follows: expired air samples were collected before administration of 75 mg of 13C-methacetin or 2 mg/Kg of 13C-aminopyrine. Breath samples were collected at 15-minute intervals for 2 hours. The 13C enrichment was measured by an isotope ratio mass spectrometer. The results were expressed as cumulative percentage of 13C recovered in breath after 2 hours (CPD2). Statistical analysis was performed with Student’s T test and ROC curve analysis. Results: MBT: The CPD2 of healthy controls and patients was 39.05% ± 5.1 and 24.1% ± 8.8, respectively (p=0.00001). Among HHT patients, MSCT indicated vascular shunts (arterio- systemic and/or arterio-portal) in 34 cases (75%). The CPD2 in controls was significantly higher than that in HHT patients with (22.5% ± 7.3 [p<0.00001]) and without (28.4% ± 6.2) p <0.05 liver involvement. The CPD2 in HHT patients with AVMs was lower than that in those without AVMs (p=0.05). Patients with a CPD2 >22% showed a 93.8% positive predictive value (PPV) to show AVMs at MSCT (specificity 90%). Regarding ABT, no difference in CPD2 values were found between controls (15.7% ± 3.1), HHT patients (16.2% ± 2.7), HHT patients with (15% ± 1.8) and without AMs (18.3% ± 3.2). Conclusions: MBT showed a high positive predictive value to identify hepatic shunts in HHT patients and could be proposed as a screening tool to select patients to be studied with hCT. By contrast, ABT, which is an indirect index of hepatocellular function, is not altered in HHT patients. Further studies are needed to correlate the MBT with alteration of the first pass effect in the liver of the HHT patients.

HEPATIC COPPER, IRON AND ZINC CONCENTRATIONS IN A NEAR HISTOLOGICAL RESOLUTION IN WILSON DISEASE DETERMINED BY MICROSCOPIC SYNCHROTRON RADIATION X-RAY FLUORESCENCE

Wolfgang Osterode1, Gerald Falkenberg2, Fritz Wrb3, Peter Ferenci4; 1Internal Medicine 2, Medical University of Vienna, Vienna, Austria; 2HASYLAB, DESY, Hamburg, Germany; 3Clinical Pathology, Medical University of Vienna, Vienna, Austria; 4Internal Medicine 3, Medical University of Vienna, Wien, Austria

Hepatic copper (Cu) is only indirectly stainable in histological slices. Therefore a fivefold increase of hepatic Cu is considered as the best available test for diagnosis of hepatic Wilson disease (WD). However Cu values from single biopsy specimen may be misleading and can not quantify regional differences. The aim of this study was to establish a method for Cu quantification (along with zinc (Zn) and iron (Fe)) using microscopic synchrotron radiation X-ray fluorescence technique (µ-SR XR). Methods: Paraffin embedded liver tissue from 7 explanted livers of WD patients and of normal liver tissue obtained at post-mortem examination of 7 subjects dying from myocardial infarction was investigated. µ-SR XR measurements were performed at beam line L of DORIS III storage ring at HASYLAB/DESY (Hamburg, Germany). A monochromatic X-ray beam was focused by a polycapillary half lens to a cross section of 15 µm for two dimensional scanning of liver slices. Position of measurements was controlled by a long-distance light microscope with a CCD camera for controlling areas of interest in comparison with histochemically prepared slices. A total of 72,000 spectra were analyzed using the AXIL program package. For quantification a Ge standard foil before and after each measurement was used as external standard. Results: As expected, Cu was about 10-fold increased in WD (263±190 ppm/g [±SD]; normal: 23; ± 5; p<0.001). Cu measured by flame atomic ab- sorption spectroscopy was 1176±737 µg/g dry weight (normal: - 50 µg/g). Cu was 7 times higher in hepatocytes (562±136) than in portal tracts (82±21). Within cirrhotic nodules copper was inhomogeneously distributed. Zn was lower in WD (59±18 vs. 89±19; p<0.05), and iron was increased (246±132 vs. 152±54; p<0.05). Fe in portal tracts was higher than in hepatocytes. Additionally, it turned out that associations between Cu, Zn and Fe were different for portal tracts and hepatocytes. Conclusion: µ-SR XR analysis is a valuable tool to measure simultaneously Cu and other metal elements in WD such as e.g. Fe and Zn. This technique (continuous scanning mode) allows a near light microscopic resolution (20x) of hepatic metal distribution. The decrease of hepatic zinc and the increase of hepatic iron content in WD reflect the interplay of copper with these metals.

Background - AAV serotypes 2 (AAV2) and 8 (AAV8) are widely used for hepatic gene transfer applications in animal models. Due to the single-stranded nature of AAV, gene targeting to correct mutations through homologous recombination (HR) has proven successful in vitro and in vivo. It is superior to episomal gene expression for site specificity and stability. Aims - To examine time course and dose responses for both serotypes to examine time course and dose responses for both serotypes

To show that AAV2 and AAV8-mediated HR can correct the metabolic liver disease hereditary tyrosinemia 1 (HT1) in vivo.

- To show that AAV2 and AAV8-mediated HR can correct the episomal gene expression for site specificity and stability.

Aims - To examine time course and dose responses for both serotypes as well as the integration stability after induction of hepatocyte (HC) turnover. Methods - We designed a vector carrying 4520 nucleotides homologous to the mouse fumarylacetoacetate hydrolase (Fah) genomic sequence with a central point mutation leading to a premature stop codon (pAAV-4k). AAV2 and AAV8 were intravenously injected into Fah5961SB mice, a model for HT1. Targeted recombination events were quantified by Fah immunohistochemistry. Results - Neonatal AAV8-4k administration resulted in faster and higher gene targeting efficiency compared to AAV2. Up to 0.3% Fah positive (Fah+) HC could be detected as early as 3 days after AAV8-4k injection. With AAV2-4k Fah+ HC could only be detected after one week at a lower frequency of about 20 / 100,000 HC. These were stable up to 4 weeks without selection. Doses from 3x108 to 2x1011 of each serotype were neonatally injected and liver tissue analyzed after 2 (AAV8) or 3 weeks (AAV2) without selection. For AAV8, 95 Fah+ HC / 100,000 HC were counted at the lowest dose (< 10 / 100,000 at the highest dose). For AAV2, 40 – 50 Fah+ cell clusters / 100,000 HC could be identified at concentrations < 4x1010. The administration of lower doses resulted in lower gene targeting efficiency. Neonatal injection of AAV2-4k, similar to AAV8-4k, led to HT1 correction after selecting for Fah+ HC for >4 weeks as measured by weight gain. After partial hepatectomy the mice exhibited clinical recovery similar to untreated controls. Recipient Fah5961SB mice undergoing serial transplantation with > 300,000 HC from clinically restored mice show Fah+ HC engraftment after 5-6 weeks of selection. This is indicative of stable HR. Conclusions - Liver directed AAV-mediated HR is feasible and stable with AAV2 and AAV8. AAV8 leads to earlier HR events than AAV2. Recombination frequencies are higher at lower vector doses. The metabolic function in a model for HT1 can be fully and stably restored by both serotypes. Studies to enhance the rate of gene targeting are currently under investigation.

Mistry9, Mario Maas10, Greg Pastores10, Anna Tylki-Szymanska11, John Yee12, Tim Cox13; 1Dept. of Internal Medicine, Gastroenterology and Hepatology, St. Franziskus-Hospital, Academic Teaching Hospital, University of Cologne, Cologne, Germany; 2University Research Medical Center, Coral Springs, FL; 3Amsterdam Medical Center, Amsterdam, Netherlands; 4Hospital Beaujon, Paris, France; 5Padiglione Granellle Ospedale Policlinico, Milano, Italy; 6King Edward Memorial Hospital, Subiaco, WA, Australia; 7National University, Taipei, Taiwan; 8Universidade de Sao Paulo, Sao Paulo, Brazil; 9Yale University School of Medicine, New Haven, CT; 10New York School of Medicine, New York, NY; 11Institut Pernik Centrum Zdrowia Dziecka, Warsaw, Poland; 12Genzyme Corporation, Boston, MA; 13University of Cambridge, Cambridge, United Kingdom; 14Childrens Hospital, Cincinnati, OH

Background: Gaucher disease, the most frequent lysosomal storage disease, is based on a deficiency of glucocerebrosidase and leads to hepatosplenomegaly, pancytopenia and disabling bone disease. Hepatic complications are elevated transaminases, cirrhosis and hepatocellular carcinoma. Enzyme therapy with intravenous infusions of macrophage-targeted recombinant glucocerebrosidase (imiglucerase) is the standard therapy with intravenous infusions of macrophage-targeted recombinant glucocerebrosidase (imiglucerase) is the standard of care for patients with symptomatic GD. Treatment requires an individualized approach to therapy and disease management. Aims: To report the frequency with which the therapeutic goals for several key clinical aspects of type 1 GD are met 4 years after starting imiglucerase. Methods: The data source was the (ICCG) Gaucher Registry, with currently more than 4.700 patients enrolled. Included were patients with type 1 GD on imiglucerase therapy for minimum 4 years, with data available at minimum 4 ± 1 years for 6 parameters: hemoglobin, platelets, liver and spleen volume, bone pain and bone crises. Goals were: Hb > 11 g/dl (for males: 12 g/dl); platelets 120.000/µl or ≥ 2x baseline value in those with baseline platelets < 60.000/µl; liver volume < 1.5 x normal, spleen volume < 8.0 x normal; bone crises absent and bone pain mild to absent. Patients were compared for the total number of therapeutic goals met of the 6 parameters. The response groups were compared by genotype group. The 6 parameters were also compared by the proportion of patients achieving the relevant therapeutic goal for each parameter. Results: 337 of a potential 1,473 patients met the inclusion criteria. Overall, 37.4% (126) had achieved all 6 therapeutic goals at the 4-year observation point. 72.1% (243) achieved at least 5 goals; 89.3% (301) achieved at least 4 goals; 98.2% (331) achieved at least 3 goals; 99.4% (335) achieved at least 2 goals. All 337 patients achieved at least one therapeutic goal. The achievement of goals varied among organ systems with 98.8% (bone crises), 91.0% (haemoglobin level), 90.0% (liver volume), 74.8% (bone pain), 76.7% (platelet count) and 69.4% (spleen volume) achieving the goal. Genotype at the glucocerebrosidase locus was not a significant determinant of treatment goal attainment. Conclusions: The therapeutic goals for anemia, thrombocytopenia, hepatomegaly, splenomegaly, bone pain and crises in type 1 GD are variably attained within the predicted intervals. The variability is not related to genotype. Definition of clearly defined clinical goals is a prerequisite of successful therapy and benchmark analysis may be used as a tool to assess whether a structured disease management approach improves outcomes in patients with type 1 GD.

FUNCTIONAL ANALYSIS OF ATP7B VARIANTS AS AN AID TO DIAGNOSIS OF WILSON DISEASE

Diane W. Cox, Susan M. Kenney, Taha M. Deeb, Georgina Macintyre; Department of Medical Genetics, University of Alberta, Edmonton, AB, Canada

We are testing the function of mutations in ATP7B, the defective gene in Wilson disease, a disorder of copper transport and accumulation. Age of onset of symptoms varies from 3 to almost 70 years, and diagnosis for this treatable disorder is challenging. Mutation analysis is a feasible and effective adjunct to clinical and biochemical features for diagnosis. We have documented all reported mutations in ATP7B in the Wilson Disease Database, that includes more than 500 variants (probable disease-causing and the remainder possible normal variants) from populations worldwide (www.medicalgenetics.med.ualberta.ca/wilson/index.php). Of 380 mutations in the database, 199 are missense, 114 insertions and deletions, 34 nonsense and 33 splice site mutations. An important aspect for diagnosis is discrimination between disease-causing variants and rare normal variants, highlighting the need for functional studies, carried out to date on only 26 of 199 missense variants. ATP7B has two major functions: first, the intracellular transport of copper to the Golgi for incorporation into proteins that require copper for normal function including ceruloplasmin; second, elimination of copper from the liver. This function requires the trafficking of ATP7B in copper-loaded vesicles to the plasma membrane of hepatocytes, to allow export of excess copper into bile. To test for the functional defects in potential ATP7B mutants, we exploit a highly conserved copper transport pathway in yeast. Human ATP7B can replace the yeast homologue, Ccc2p, and allows for normal copper transport in ccc2p yeast strains. Copper is then available for incorporation into Fet3p (ceruloplasmin homologue) that imports iron into yeast. Normal transport function is assessed by growth on low iron media. Variants that do not support normal copper transport function, do not grow on low iron media, and are considered ATP7B mutations. Variants that display a specific trafficking defect, and are tested in mammalian copper cytotoxicity and trafficking assays, using CHO cells stably transfected with ATP7B or variants. 3D-protein modeling allows an assessment of the potential impact of amino acid changes upon ATP7B protein structure and function. We studied ten additional mutants in ATP7B in potential ATP7B mutants, we exploit a highly conserved copper transport pathway in yeast. Human ATP7B can replace the yeast homologue, Ccc2p, and allows for normal copper transport in ccc2p yeast strains. Copper is then available for incorporation into Fet3p (ceruloplasmin homologue) that imports iron into yeast. Normal transport function is assessed by growth on low iron media. Details of the intracellular site at which replication of HEV occurs is unknown. This study attempts to explore the intracellular site of HEV replication by localizing HEV Replicase in transfected HepG2 cells. Methods: In-frame fusion construct of replicase-enhanced green fluorescent protein (EGFP) gene was made in eukaryotic expression vector. Stable transfected cells expressing Replicase-EGFP fusion protein were generated. The functionality of this protein was determined by its ability to synthesize negative sense HEV RNA. Positive sense HEV transcript was used as a template to demonstrate synthesis of negative sense HEV RNA in the replicase-EGFP expressing stable transfected cells, by strand specific anchored RT-PCR. It was also confirmed with the use of anti-sense strand specific molecular beacon. Sequence analysis and structure prediction of HEV replicase identified possible membrane binding helices. Subcellular co-localization was investigated with several organelle specific fluorescent protein expressing plasmids and fluorophores using confocal microscope. Transfection of alexa 548 UTP labeled 3’ end of HEV RNA in Replicase-EGFP expressing stable transfected cells, was used to detect the in vivo interaction between Replicase and the 3’ cis-acting elements by Fluorescence Resonance Energy Transfer (FRET) analysis. Deletion constructs of predicted membrane binding helices of Replicase, fused with EGFP were used for their role in subcellular localization analysis. immuno-electron microscopy was used to further confirm localization of HEV replicase. Results: The results show that EGFP fused Replicase was functionally active and could synthesize negative sense HEV RNA as demonstrated by strand specific anchored RT-PCR and binding to anti sense specific sense beacon emitting the Fluorescence. HEV replicase was found to localize on the membrane of endoplasmic reticulum (ER) and loss of localization was observed when the region with predicted membrane binding domain at the carboxy terminal end of replicase was deleted. FRET analysis showed subcellular interaction of Replicase with the 3’ cis-acting elements on HEV RNA in live cells. Conclusions: Based on these observations it is believed that in Hepatitis E virus, endoplasmic reticulum is the site of Replicase localization and possible replication as in many other positive sense RNA genome containing Viruses.

2005-2006. The patient population consisted of Asian/Pacific Islanders (26.1%), Blacks (12.7%), Hispanics (42.3%), Native Americans (0.2%), and Whites (7.0%). 69.6% were foreign born. Among the 18,457 patients, 42.4% (7,826) were screened for HBsAg. 1026 (71.8%) of 1429 persons with elevated ALT were screened for HBsAg compared to 5826 (49.6%) of 11749 with normal ALTs, p<0.01. The screening rate was greatest for those 19-24 years of age (47.7%) and 25-29 years of age (48.5%), decreased among age group 30-34 (44.4%), 35-39 (41.3%), 40-44 (37.0%) and least among the eldest group, 45-49 (34.4%), p for trend<0.01. Women were slightly more likely to be tested than men (43.4% vs. 41.3%, p<0.01). A higher rate of APIs were screened (65.6%) than Blacks (38.8%), Hispanics (33.4%), Whites (32.1%) and Native Americans (28.3%), p<0.01. Among patients born in regions with high rates of HBV infection (>8%), those born in East Asia countries had the highest screening rate (692/1088, 63.6%) followed by Southeast Asia (153/304, 50.3%), and Africa (230/521, 44.1%). Patients born in regions of intermediate HBV endemicity (2.7%) including Eastern Europe, South Asia, Middle East, Central America, South America, and the Caribbean had screening rates of 35.5-40.1%, comparable to rates for patients born in the U.S. (39.5%). The screening rates varied greatly among individual clinics, highest (1040/1810, 57.5%) at community clinics which served large numbers of APIs and lowest (25/212, 11.8%) at a community clinic which served large numbers of Hispanics. This pilot study revealed that screening for HBsAg was correlated with elevated ALT, younger age, Asian race and region of birth with HBV epidemic. However, nearly 50% of patients from countries where HBV infection is endemic, and for whom screening is recommended by the CDC, had not been tested. More rigorous efforts will be necessary to increase compliance for HBV screening in this group of patients in order to decrease long-term morbidity and mortality.

1455 INSULIN RESISTANCE AND SEVERITY OF FIBROSIS IN HCV GENOTYPE 1 CHRONIC HEPATITIS
Salvatore Petta1, Calogero Cammà1, Vito Di Marco1, Nicola Alessi1, Francesco Barbaria1, Daniela Cabibi2, Rosalia Caldarella2, Giuseppe Tarantino1, Francesco Vitale3, Antonio Craxi1;
1Cattedra di Gastroenterologia, University of Palermo, Palermo, Italy; 2Cattedra di Anatomia Patologica, University of Palermo, Palermo, Italy; 3Cattedra di Igiene, University of Palermo, Palermo, Italy

BACKGROUND AND AIMs Patients with HCV G1 chronic hepatitis often have insulin resistance (IR), either due to metabolic causes and associated to visceral obesity or linked to virus-induced phenomena and non-metabolic. IR is central in the pathogenesis of steatosis, but contrasting data exist on its direct role in the progression of fibrosis. We aimed to assess whether the presence and degree of IR are linked to the stage of liver fibrosis in chronic hepatitis C genotype 1 patients. Methods Two hundred and one consecutive patients (11.04±12.06) with HCV G1 chronic hepatitis, all naive to antiviral therapy and abstinent from alcohol, were evaluated by biopsy and by anthropometric and metabolic measurements including IR assessed by the homeostasis model assessment (HOMA) score. Non-diabetic patients were defined as insulin resistant if HOMA-IR>2.7. A single pathologist graded all liver biopsies (>15 mm) by Scheuer’s score. Steatosis was graded as absent (<5% of hepatocytes) or present. Results Twenty-nine patients were diabetic (Group 1), 76 insulin resistant, non diabetic (Group 2), and 96 non diabetic, non insulin resistant (Group 3). Mean waist circumference was comparable among the three groups (Group 1, 96.5±14.6 cm; Group 2, 94.2±11.7 cm; Group 3, 90.8±10.6 cm; p=0.08), while a significant difference was found in the mean age (Group 1, 60.2±6 yrs; Group 2, 54±11 yrs; Group 3, 49±13 yrs; p=0.0003). Steatosis was present in 62% of patients in group 1, 63% in group 2 and 34% in group 3 (p=0.0006), and severe necroinflammatory activity (>1 by Scheuer) in 90%, 75% and 65% (p=0.034). Severe fibrosis (>2 by Scheuer) was found in 59%, 30% and 15% of patients (p=0.0001) in group 1, 2 and 3. At multivariate analysis severe fibrosis was independently linked to the degree of IR (OR 2.692; 95%CI 1.463-4.954), to a high necroinflammatory activity (OR 2.944; 95%CI 1.422-6.098), to platelet counts <140.000 mln (OR 7.170 95%CI 3.000-16.700), to low cholesterol (OR 0.987; 95%CI 0.976-0.998) and to high ferritin (OR 1.002; 95%CI 1.000-1.003). Conclusions In subjects infected by HCV genotype 1, a state of metabolic insulin resistance, regardless of the presence of clinically overt diabetes, and a high necroinflammatory activity are strongly linked to advanced fibrosis. Severity of IR may thus be used in nonfibrotic or mildly fibrotic HCV G1 patients as a predictor of a high risk of progression into more severe stages of fibrosis.

1456 INTERLEUKIN 12B GENE POLYMORPHISM AND APPARENT RESISTANCE TO HCV INFECTION
Doña M. Hegazy1, Prem H. Thrairajah1, Magdalena Metzner1, Annwyne Houldsworth1, Edward Kaminski2, Andy Demaine1, Matthew E. Cramp1, Institute of Biomedical and Clinical Sciences, Peninsula Medical School, Plymouth, United Kingdom; 2Immunology, Derriford Hospital, Plymouth, United Kingdom; 3Hepatology, Derriford Hospital, Plymouth, United Kingdom

Background: Identifying mechanisms of protection from hepatitis C virus (HCV) infection remains a key research goal. We have identified a cohort of cases at very high risk of HCV infection through injection drug use but who remain both HCV antibody and HCV RNA negative. We have termed these ‘exposed uninfected’ (EU) cases. Interleukin 12 (IL-12) is a key cytokine that promotes anti-viral T helper 1 (Th1) responses. A functional IL-12p40 polymorphism has been associated with spontaneous clearance of HCV infection and we hypothesised that a genetic background able to promote cellular responses may be associated with apparent protection from infection. Methods: We identified 76 EU cases from long-term injection drug users who tested both HCV antibody and HCV RNA negative despite reported risk behaviour. The IL-12 p40 polymorphism was studied using restriction fragment length genotyping and findings compared to 105 healthy controls. Results: The high IL-12 producing ‘C’ allele was found in 27.6% of exposed uninfected cases compared to 16.7% of healthy controls (χ² = 6.3, p = 0.01, RR= 1.7). Conclusions: Individuals at high risk of HCV infection yet who remain uninfected may be resistant to infection. In our cohort of exposed uninfected cases a genetic background of enhanced IL-12 production was associated with apparent resistance to HCV infection. This lends support to a central role for cellular immune responses in protecting from infection.

GBV-C CO-INFECTION IN HIV PATIENTS IS ASSOCIATED WITH LOW CCR5 AND CXCR4 SURFACE EXPRESSION ON CD4+ CELLS

Carolynne Schwarze-Zander, Markus Neibecker, Sabrina Othman, Carolin Welzel, Monika Schulz, Esther Voigt, Martin Vogel, Jan-Christian Wasmuth, Guido Luechters, Tilman Sauерbruch, Juergen Rockstroh, Ulrich Spengler; Department of Internal Medicine I, Bonn, Germany

Background: The flavivirus GBV-C, not known to cause any disease, has been associated with delayed progression of HIV disease. Recently, in vitro studies demonstrated down-regulation of CCR5 as a potential mechanism of GBV-C to modulate HIV disease. We therefore studied surface expression of the two major HIV co-receptors, CCR5 and CXCR4, on CD4+/CD8+ T-cells in 128 HIV patients stratified with respect to GBV-C status and immune function. Methods: GBV-C infection was studied in 128 HIV patients by RT-PCR. CCR5Δ32 mutation was analyzed by real-time PCR. FACS analysis was used to measure CCR5 and CXCR4 surface expression on CD4+/CD8+ T-cells. Results: GBV-C RNA replication was detected in 30% (38/128) of patients. Fourteen patients were excluded from the analysis because of reduced CCR5 surface expression due to a heterozygous CCR5Δ32 mutation. In the remaining HIV/GBV-C co-infected patients with CD4 <200/µl CCR5 and CXCR4 expression on CD4+ T-cells was significantly reduced to 77% and 80%, respectively, of levels measured in HIV mono-infected patients (p<0.05). In contrast, HIV-monoinfected and HIV/GBV-C co-infected patients did not differ with respect to CCR5 and CXCR4 expression on CD4+ T-cells in the subgroup with preserved immune function (CD4>200/µl) and on CD8+ T cells independent of immune function. Conclusions: GBV-C co-infection is common in HIV infected patients and is associated with reduced expression of both major HIV co-receptors on CD4+ T-cells in the subset of HIV patients with advanced immunodeficiency. Therefore, the molecular and cellular mechanisms underlying down-regulation of HIV co-receptors in GBV-C co-infection merit further investigation.

Disclosures: The following people have nothing to disclose: Carolynne Schwarze-Zander, Markus Neibecker, Sabrina Othman, Carolin Welzel, Monika Schulz, Esther Voigt, Martin Vogel, Jan-Christian Wasmuth, Guido Luechters, Tilman Sauерbruch, Juergen Rockstroh, Ulrich Spengler.
23 patients IP-10 values were significantly lower than in patients without anti-HCV activity in their plasma (250.1 pg/ml and 651.3 pg/ml respectively, p<0.01). This is of importance, since recent studies identify a low pretreatment IP-10 as predictive of sustained viral response to Peg-IFNα-2a/Ribavirin combination therapy. CONCLUSIONS: The HCV-replicon based bioassay allows us to identify host-derived anti-HCV activity in heparinized plasma of CHC patients prior to treatment. This could be of great importance in a better understanding of the host response to antiviral treatment. A next step will be to investigate plasma samples of these patients during treatment.

DIFFERENTIAL ROLE OF LIVER-TARGETED REGULATORY T CELL TO HEPATITIS B AND C VIRUS IN CHRONICALLY INFECTED PATIENTS
Hisamitsu Miyaoaki, Tatsuki Ichikawa, Kazuhiko Nakao, Hidetaka Shibata, Motohisa Akiyama, Satoshi Miuma, Yasuhide Motoyoshi, Masumi Fujimoto, Katsumi Eguchi; The First Department of Internal Medicine, Nagasaki University School of Medicine, Nagasaki, Japan

Regulatory T cells play a critical role in chronic virus infection. The role of regulatory T cell in chronic hepatitis B and chronic hepatitis C is unknown. We examined the distribution and frequency of Foxp3 positive regulatory T cell in the liver tissues and compared the clinicopathological characters of HBV and HCV. Liver needle biopsies were collected from 26 patients with hepatitis B surface antigen positive (mean age:33.6±10.4, male:female=23:3) and 27 patients with hepatitis C virus antibody positive (mean age:57.8±10.6, male:female=15:12). In each liver tissues, T cells were examined with anti-CD3 antibody (Novocastra, Newcastle, UK) and regulatory T cells were examined with anti-Foxp3 antibody (eBioscience, San Diego, CA, USA). The average proportions of Foxp3+ Tregs among the total number of CD3+ T cells in each portal tracts was determined. The ratio of Foxp3 in CD3 was similar in HBV and in HCV cases (HBV: HCV = 0.98±0.04:0.90±0.05). In HBV cases, there was significant correlation between the ratio of Foxp3 in CD3 and serum ALT level (P=0.025, r=0.402). The ratio of Foxp3 in CD3 was significantly increase in severe activity group than in mild activity group (mild:severe=0.08±0.03:0.11±0.04, P=0.04). There were no significant differences in the ratio of Foxp3 in CD3 in HBV cases among the other clinical factors (age, gender, platelet, fibrosis, HBVDNA viral load). In HCV cases, the variables that were significantly associated with the ratio of Foxp3 in CD3 were:

- Gender: Male (male:female=0.07±0.03:0.11±0.05, P=0.002)
- Serotype 1 (serotype1:serotype2=0.07±0.04:0.15±0.05, P=0.0002)
- Age (male:female=0.07±0.10.03:0.11±0.05, P=0.04)

These factors were easy sensitivity factors for interferon therapy. There were no significant differences in the ratio of Foxp3 in CD3 in HCV cases among the other clinical factors (age, ALT level, platelet, activity, fibrosis, HCV viral load). In conclusions, these data provided the impaired of regulatory T cell function cause acute exacerbation in chronic hepatitis B. On the other hand, regulatory T cell may be related with action of interferon in chronic hepatitis C.

SUCCESSFUL USE OF HEPATITIS C POSITIVE KIDNEYS FOR TRANSPLANTATION: CAUTION ON THE USE OF OLDER DONORS
Mary T. Killackey, Kyle Fargen, Tareq Islam, Anil Paramesh, Rubin Zhang, A Brent Alper, Shobha N. Joshi, Fredric G. Regenstein, Douglas Slakey, Sander Florman; Surgery-Transplant and Hepatobiliary Surgery, Tulane University, New Orleans, LA

Recent data is scarce regarding the use of HCV+ donor allografts in HCV+ kidney recipients. Review of the literature demonstrates there is benefit to proceeding with transplant. However, outcome analysis suggests patient and graft survival to be lower in this population. The natural history of HCV and liver disease progression is unclear. HCV+ donors account for 5% of all donors in the United States. A few small studies suggest outcomes to be similar to those HCV+ recipients receiving HCV- organs. There is little or no data on the selection criteria of HCV+ donors. The present study reports our experience and provides suggestions for donor selection. Patients & methods: Since 1996, 41 HCV+ patients underwent deceased donor kidney transplant with an HCV+ donor organ. Only well-compensated patients with genotype 1 and a measurable viral load were offered these organs. Two patients were excluded due to graft loss within the first week, leaving 39 patients to be evaluated for longterm (3 year) follow-up. Mean age of the recipients was 49 years, with the majority being male (79%) and African-American (85%). HTN was present in 97% and DM in 28%. Mean time of cold ischemia was 18 hours. Perioperative biopsy of the donor kidney was available in 29 patients. Standard, triple drug immunosuppression was used without induction. Statistical analyses were performed using SAS 9.1.3. Results: The overall incidence of acute rejection during the study period was 11/100 person year. Patient and graft survival at 1 year was 100% and 94.6% and at 3 years, 84.4% and 79.3%, respectively. This is comparable to our overall patient and graft survival. Outcome analysis was performed in recipients who received a donor organ < 49 years as compared to older donors. Overall incidence of graft loss and death was higher in the older donor group. While not powered to be statistically significant, the trend is clear. In donors ≥49 years, the overall incidence of graft loss and death was 27% and 18% as compared to 11% and 7% in younger donors. Biopsy review in donors > 49 years found 4/6 (67%) to have >15% fibrosis as compared to 2/16 (12.5%) in younger donors. Conclusion: Use of HCV+ kidney donors remains a viable option for HCV+ recipients but requires careful donor selection. We advocate that HCV+ donors > 49 years should not be considered for transplant as the kidneys seem to have worse outcomes and more advanced fibrosis. Furthermore, HCV+ recipients are frequently transplanted with short waiting times obviating the need to use older donors.

BILE DUCT DILATION IN HEPATITIS PATIENTS ON CHRONIC METHADONE THERAPY
Trinh Meyer, Denis Kapkov, Michael Lipp, Douglas Meyer, Henry C. Bodenheimer, Albert Min; Division of Digestive Diseases, Beth Israel Medical Center, New York, NY

Methadone maintenance therapy is commonly used in the treatment of intravenous drug users (IVDUs). Zybelberg et al. showed that methadone may lead to dilated common bile duct...
(CBD). We tried to assess this hypothesis in a large group of asymptomatic hepatitis B (HBV) and/or hepatitis C (HCV), ex-IVDU patients on chronic methadone therapy with age- and gender-matched control group of patients with HBV and/or HCV of similar severity by using abdominal imaging tests. Methods: Charts of all adult patients with HBV and/or HCV with and without methadone between January 2002 and 2007 at GI and ID clinics at our center were reviewed. The data collected were age, gender, size of CBD (with ultrasound and MRI), cirrhosis, AST, ALT, ALP, bilirubin (Tbi), dose and duration of methadone. Patients with history of pancreatitis, cholelithiasis and cholecystectomy were excluded from the study. Data were analyzed using t-test, chi-square test and Fisher’s exact test. Results: There were a total of 215 HCV and/or HBV patients (70% males, mean age 47.3 ± 7.3 years) in the methadone study group and 108 patients (71.3% males, mean age 49.6 ± 8.7 years) in the control group. The size of CBD in the study group was statistically significantly more dilated than the control group (5.87 mm vs. 3.79 mm, p<0.0001). Dilated CBD (CBD ≥ 8mm) were seen in 26.1% and 2.78% of study and control group, respectively (p < 0.0001). Normal size bile duct were seen in 55.3% and 89.8% of the study and control group, respectively (p <0.0001). AST, ALP, Tbi, cirrhosis and history of alcohol were significantly higher in the study group than the control group.

Conclusion: Chronic methadone therapy may cause dilated CBD in this population. Patients with history of pancreatitis, cholelithiasis and cholecystectomy were excluded from the study. The data collected were age, gender, size of CBD (with ultrasound and MRI), cirrhosis, AST, ALT, ALP, bilirubin (Tbi), dose and duration of methadone. Patients with history of pancreatitis, cholelithiasis and cholecystectomy were excluded from the study. Data were analyzed using t-test, chi-square test and Fisher’s exact test. Results: There were a total of 215 HCV and/or HBV patients (70% males, mean age 47.3 ± 7.3 years) in the methadone study group and 108 patients (71.3% males, mean age 49.6 ± 8.7 years) in the control group. The size of CBD in the study group was statistically significantly more dilated than the control group (5.87 mm vs. 3.79 mm, p<0.0001). Dilated CBD (CBD ≥ 8mm) were seen in 26.1% and 2.78% of study and control group, respectively (p < 0.0001). Normal size bile duct were seen in 55.3% and 89.8% of the study and control group, respectively (p <0.0001). AST, ALP, Tbi, cirrhosis and history of alcohol were significantly higher in the study group than the control group.

Conclusion: Chronic methadone therapy may cause dilated CBD. Dilated CBD was statistically significantly associated with the duration of methadone (p<0.01), but not the dose of methadone (p =0.83). On average, the patients with dilated CBD were on methadone for 33 months versus 23 months in the normal size CBD patients. Multivariate logistic regression of the data showed that patients on chronic methadone are 17.5 times more likely to develop dilated CBD (Odds Ratio=17.5). Conclusion: Chronic methadone therapy may cause dilated CBD. Dilated CBD was significantly correlated with the duration of methadone. Greater awareness is needed of the potential association between bile duct dilation and chronic use of methadone. Therapeutic intervention of biliary dilation in this specific group of patients may be unnecessary.

PRESENCE OF HEPATIC PROGENITOR CELLS IN HUMAN CHRONIC LIVER DISEASES AND RELATION TO HEPATOCELLULAR CARCINOMA DEVELOPMENT

Athanassios C. Tsamandas1, Konstantinos Thomopoulos2, Dimitra Dimitropoulou2, Ioulia Syrrokosta2, Theodore Petsas2, Chrisoula Karatza2, Charalambos Gogos2; 1Pathology, University of Patras School of Medicine, Patras, Greece; 2Medicine, University of Patras School of Medicine, Patras, Greece; 3Radiology, University of Patras School of Medicine, Patras, Greece

Aim: This study assesses the potential role of hepatic progenitor cells (HPC) presence and relation to hepatocellular carcinoma (HCC) future development in patients with chronic liver disease (CLD). Methods: The study included 52 liver biopsies obtained from 52 patients with CLD assigned in 2 groups (26 each). Group A: chronic hepatitis B (HBV-A1-n=9), chronic hepatitis C (HCV-A2-n=5), genetic hemochromatosis (GH-A3-n=5), and alcoholic liver disease (ALD-A4-n=7). These 26 patients developed HCC (confirmed by liver biopsy) in a 1-5 (median 3) year period after the time of the initial biopsy. None of these 26 patients had HCC at the first time. Group B: 26 biopsies: HBV (B1-n=9), HCV (B2-n=3), GH (B3-n=5) and ALD (B4-n=7).

Patients of group B did not develop HCC at the same time period. Liver biopsies were matched for inflammation grade and fibrosis stage: subgroup A1 to B1, A2-B2, A3-B3, A4-B4. Paraffin sections were subjected to a) immunohistochemistry using antibodies for CK19, LCA, CD34 and b) in-situ hybridization for alpha fetoprotein mRNA detection. Cells with morphologic features of HPC (Roskams T et al Hepatology 39:1739, 2004) that were CK19+/AFP+ and LCA(-)/CD34(-) were scored. In addition, we performed gene analysis for AFP mRNA, on dissected tissue samples removed from liver sections that included areas with HPC expression, as this was described above. Results: The table lists the results for CK19 and AFP mRNA expression. Similar results were obtained from AFP gene analysis. The numbers of HCC were directly correlated with i) inflammation degree (p<0.01) and ii) fibrosis stage (p<0.01).

Conclusions: This study shows that HPC are frequently present in CLD cases and their numbers are directly related to the severity of the disease. The fact that biopsies of group A (cases that developed HCC in the future) showed significantly higher HPC numbers, supports the hypothesis that HPC proliferation is associated with increased risk for hepatocellular carcinoma. Further studies are needed to determine if the increased expression of HPC in CLD cases predicts the risk for future development of HCC in such cases.

WHAT MOTIVATES PRIMARY CARE PROVIDERS TO TEST FOR HCV?

Maricruz Velez1, David N. Assis2, Marta Alvarez-Posadilla3, Steven K. Herrine1, Simona Ross1, Victor J. Navarro1; 1Division of Gastroenterology & Hepatology, Thomas Jefferson University, Philadelphia, PA; 2Department of Medicine, Thomas Jefferson University, Philadelphia, PA; 3Sección de Aparato Digestivo, Hospital de León, León, Spain

Background: HCV testing is uncommon in primary care; risk factor ascertainment is even less frequent (Trooskin, 2007). Little is known about why this behavior exists and whether HCV testing is regarded as a priority in primary care. The aims of this study were to explore motivations for HCV testing in primary care, to survey the perceived priority of HCV testing, and to identify practice characteristics associated with the likelihood of testing. Methods: A survey was mailed to 2,365 primary care providers in the Philadelphia area. The survey ascertained provider and practice characteristics, HCV risk assessment and testing strategies, and the perceived importance of HCV risk assessment and testing. Results: A total of 1,219 surveys were returned (58% response). The mean age of respondents was 50 years, 73% were male
and 83% were non-Hispanic White. Fifty-one percent were interns; 67% were in private practice, 59% were in a suburban area. Ninety-six percent reported routinely asking about drug use and 58% reported routinely asking about blood transfusions. Abnormal ALTs were cited as the most common reason for HCV testing (83%), followed by patient symptoms (60%), positive HCV antibody after blood donation (56%), physician-ascertained HCV risk factor (54%), and patient-requested testing (48%). Providers with predominately Black/Hispanic patient populations were more likely than providers with predominantly White populations to report patient risk factors as a motivation for HCV testing [p<.05]. The likelihood of HCV testing based on patient risk factors and elevated ALTs increased with the number of patients with a history of drug use seen by the provider [p<.05]. Seventy-six percent of the providers reported that risk factors for HCV should be ascertained routinely, and HCV testing should be offered to those at risk, while 13% reported that HCV testing should be offered to all patients.

Conclusion: Although providers recognize the importance of identifying HCV risk factors and risk factor based testing, our data show that most testing is not motivated by physician identified risk factors. Rather, abnormal ALTs serve as the most common motivation for testing. The chasm between providers' perceived importance of HCV risk factor ascertainment and testing and their reported testing strategies may, in part, be attributable to differing practice characteristics. Testing based on lab abnormalities is insensitive and may fail to identify infected persons. To increase detection of patients with HCV, risk factor ascertainment must be integrated into standard practice, irrespective of practice characteristics.

CD4-CD8- T CELLS CONTRIBUTE TO THE PERSISTENCE OF MHV-3 INDUCED CHRONIC VIRAL HEPATITIS
Jiangguo Zhang, Hongwu Wang, Weiming Yan, Xiaojing Wang, Dong Xi, Xiaoping Luo, Qin Ding: Department of Infectious Disease, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Objective: To study the contribution of T cell subsets to the pathogenesis in MHV-3 induced chronic viral hepatitis in C3H/Hej mouse. Methods: In this work, ninety C3H/Hej mice individually received 10 plaque forming units (PFU) of MHV-3 intraperitoneally. The ratios of T cell subsets including CD3+CD4+CD8-, CD3+CD4-CD8+, CD3+CD4-CD8- (DNT cells), CD3+CD4+CD25+, CD3+CD4+CD25-, CD3+CD4-CD25+, CD3+CD4-CD25+ T lymphocytes in total T lymphocytes in blood, spleen and liver were examined at 0,2,4,6,8,10,12,15,20,25,30,40 days post MHV-3 infection by flow cytosorting. Magnetic bead sorting was applied for the purification of T cell subsets. The cytotoxic effects of DNT cells and CD4+CD25-T cells on both CD8+T cells and hepatocytes were examined by CytoTox96 Non-Radioactive Cytotoxicity Assay at 0, 4, 15, 30, 40 days post MHV-3 infection. Results: The DNT cell and CD4+CD25-T cell ratios raised significantly since 2 days post MHV-3 infection in C3H/Hej mice, and CD3+CD4+CD8-, CD3+CD4+CD8-, CD3+CD4-CD25-, and CD3+CD4-CD25- T cell ratios decreased accordingly. DNT cells showed significant cytotoxic effects on CD8+T cells with a cytotoxic rate of 97.00%±0.01%, while CD4+CD25+T cells only had slight cytotoxic effects on it with a cytotoxic rate of 51.27%±0.01%. Conclusions: Here we first report that DNT cells, rather than CD4+CD25-T cells, have more profound immune modulatory effect on CD8+T cells in MHV-3 induced chronic viral hepatitis in C3H/Hej mice, suggesting their contribution to viral persistence. Further characterizations of DNT cells are under studying. This study was supported by NSFC 3057164, 30672380 and National Key Basic Research Program of China (2005CB522901).

COMPLETE GENOME SEQUENCES AND PHYLLOGENETIC ANALYSIS OF HEPATITIS D VIRUSES (HDV) ISOLATED FROM TURKISH PATIENTS WITH CHRONIC HDV INFECTION
Filibiz Emir1, Mehmet Bektas2, Ela Kesen1, Ramazan Ildimon1, A.Mithat Bozdaiy1,2, Cihan Yurdadaydin1,2,1 Hepatology Institute, Ankara University, Ankara, Turkey; 2Department of Gastroenterology, School of Medicine, Ankara University, Ankara, Turkey

Hepatitis Delta virus (HDV) infection is a global health problem with more than 10 million infected people. Phylogenetic relatedness and different genotypes of HDV which vary with respect to geographical distribution may affect the overall clinical outcome of the disease. In this study, we aimed to find out the complete nucleotide sequence of HDV genomes isolated from 5 naive Turkish patients and to perform phylogenetic analysis of these genomes. Five naive HDV-infected Turkish patients (3 male, 2 female; median 52 years old) were included in the study. Twelve pairs of primers were used in order to amplify six overlapping fragments covering the whole HDV genome by RT-nested PCR. The overlapping PCR products were then sequenced using ABI PRISM 310 Genetic Analyzer and the complete HDV genome sequences were determined. Phylogenetic analysis was performed using MEGA 3.1 software by UPGMA (Unweighted Pair Group Method with Arithmetic mean). The reference sequences obtained from GenBank database are from France, USA, China, Japan, Peru, Iran, Lebanon, Italy and 3 sequences from Taiwan. Results of direct sequencing revealed that all 5 HDV genomes were genotype 1 and consisted of 1676 nucleotides encoding the hepatitis delta antigen (HDAg) of 214 amino acid in length. Based on phylogenetic tree, all Turkish patients were dispersed through the same branch with 2 Taiwanese, French, Italian, Chinese, and Iranian sequences with a bootstrap value of 99%. One of the Taiwanese sequences was closest to the Turkish sequences. The American, Japanese, and Peruvian sequences were phylogenetically far away from Turkish sequences with a 68% bootstrap value. Data analysis confirmed genetic heterogeneity of the hepatitis delta virus.

QUANTITATIVE DETECTION OF INTEGRATED HBV SURFACE GENE SEQUENCES IN THE LIVER BY REAL-TIME PCR
Andreas Laras1, Aggeliki Kostamena1, Stephanos J. Hadziyanis1,2,1 Hepatitis Research Laboratory, University of Athens, Athens, Greece; 2Dept. Medicine and Hepatology, Henry Dunant Hospital, Athens, Greece

Introduction: Chronic hepatitis B (CHB) patients under long-term nucleos(t)ide analogue treatment may achieve profound...
HBV suppression with non-detectable serum HBV DNA and low intrahepatic cccDNA levels. Continuing surface antigen expression observed in these patients could be attributed to transcribed integrated HBV DNA harbouring intact surface antigen (S) gene sequences. **Aim:** To develop a quantitative method for the detection of integrated HBV DNA harbouring S sequences in the liver of CHB patients under suppressed HBV replication and to evaluate its performance in liver biopsy samples of patients under long-term antiviral therapy. **Methods:** Liver biopsy specimens from 20 CHB patients in profound HBV suppression under nucleos(t)ide analogue treatment were tested for integrated HBV S gene sequences using specifically designed real-time PCR assays that simultaneously measure intrahepatic HBV DNA in the S and the core promoter-precore (CP-preC) regions. HBV integration occurs predominantly in the CP-preC region of the viral genome leaving S sequences sequences frequently intact. Cloned and serum HBV DNA were used as controls. Intrahepatic HBV S gene expression was also measured. HBsAg and HBeAg expression was also assessed in the same biopsy samples by immunohistochemical methods. **Results:** Low HBV cccDNA levels were found in all patients, median 0.31 (range 0.05-0.84) copies/cell. In fact, cccDNA was the predominant form of viral DNA representing on the average 79% of total intrahepatic HBV DNA. These conditions permitted quantitation of low copy integrated HBV sequences. Total intrahepatic HBV DNA levels measured in the S region were significantly higher than in the CP-preC region, 0.70 (0.10-2.65) vs 0.38 (0.05-1.74). In 11/20 patients, as well as in cloned and serum HBV DNA controls, there was no discrepancy between the two measurements. In 9/20 patients S levels were significantly higher (2-fold to 13-fold) than the corresponding CP-preC measurements (0.71 vs 0.20). In these patients, integrated HBV S sequences were detectable in significant levels, 0.51 (0.17-1.4) cp/cell. Consistent with these findings were the results of histochemical demonstration of HBsAg proteins in the same liver samples. **Conclusions:** 1. We have developed a method for quantitative detection of integrated HBV DNA harbouring S gene sequences in liver biopsy samples. 2. This method can only be used in situations of highly suppressed viral replication permitting detection of low copy integrated S sequences. 3. Integrated HBV S sequences were detectable in approximately 50% of treated patients with compatible findings in immunohistochemical observations of HBsAg expression in the liver.

### 1469 CHRONIC LIVER DISEASE AMONG ALASKA NATIVE PEOPLE, 2003-2004

Gayle Fischer1, Stephanie R. Bialek1, Chris Homan2, Stephen Livingston3, Brian J. McMahon3,4; 1Division of Viral Hepatitis, Centers for Disease Control and Prevention, Atlanta, GA; 2Alaska Native Medical Center, Anchorage, AK; 3Liver Disease and Hepatitis Program, Alaska Native Medical Center, Anchorage, AK; 4Arctic Investigations Program, Centers for Disease Control and Prevention, Anchorage, AK

**Purpose:** The proportion of deaths attributable to chronic liver disease (CLD) is four times higher among American Indian (AI)/Alaska Native (AN) people compared to other racial/ethnic groups in the United States, but the epidemiology in this population is not well described. We report the findings of a cross-sectional study of CLD prevalence and its etiologies among AN and AI people. Methods: The study population included AN and AI people ≥18 years old in the Anchorage area who had ≥1 inpatient or outpatient visit at the Alaska Native Medical Center (ANMC) from 2003-2004. ANMC provides primary and specialty care to eligible AI and AN people. CLD was defined as having either: 1) an ICD-9 code indicating CLD; or 2) ≥2 elevated alanine aminotransferase (ALT>40IU/L), aspartate aminotransferase (AST>40IU/L), or gamma-glutamyl transpeptidase (GGT>50IU/L) levels ≥3 months apart or 3) both. CLD etiologies were assigned using ICD-9 codes and clin-
ical test results. Persons could have more than one etiology. Results: The prevalence of CLD was 7.3% (1903/26,166). Among those with CLD, 88% were AN people, 51% were female, 80% were urban residents, and the mean age was 46 years. The most common etiologies were alcohol-related liver disease (42%), non-alcoholic fatty liver disease (NAFLD) (29%), chronic hepatitis C virus (HCV) infection (26%) and chronic hepatitis B virus (HBV) infection (8%). 11% had both alcohol-related liver disease and chronic HCV infection. Males compared to females had a higher prevalence of CLD (82.7 vs. 65.3 per 1000; p=0.001), alcohol-related liver disease (36.4 vs. 24.9 per 1000; p=0.001), chronic HCV infection (21.0 vs. 17.3 per 1000; p=0.03) and NAFLD (21.4 vs. 20.9 per 1000; p=0.01). The death rate from CLD was higher among females than males (2.7 vs. 1.5 per 1000; p=0.05), with females twice as likely to die from alcohol-related liver disease (2.3 vs. 1.1 per 1000; p=0.02). Conclusions: The prevalence of CLD was 7.3% among AI and AN Anchorage area residents receiving care at ANMC. Alcohol-related liver disease, NAFLD and chronic HCV infections were the leading causes. Females were less likely than males to have CLD, but were more likely to die from it. Previous reports have shown females to be more susceptible to alcohol-related liver disease than males. The frequency of complications from HCV and HBV may rise as the infected population ages, but treatments for viral hepatitis available at ANMC may reduce disease burden. Increasing rates of diabetes and obesity in AN people may result in a higher burden of CLD due to NAFLD in the future.

TEN YEAR FOLLOW-UP OF 126 CONSECUTIVE ITALIAN PATIENTS WITH HEPATITIS DELTA (HDV)-RELATED COMPENSATED CIRRHOSIS
Raffaella Romeo, Angelo Sangiovanni, Ersilio Del Ninno, Massimo Colombo; Gastroenterology, Maggiore Hospital, Milan, Italy

Background: Data have been accumulating, showing that chronic infection with HDV is less aggressive than previously reported, often leading to slowly evolving almost inactive compensated cirrhosis. Aim: to give more insights into the evolutionary course of patients with HDV-related compensated cirrhosis. Patients: 126 consecutive patients with HDV compensated liver cirrhosis, diagnosed between 1985 and 2005, were followed for a mean of 121 months (range 10-240). There were 100 males, mean age was 42 yrs (range 23-73); 93 patients (74%) were Child-Pugh A and 33 were Child-Pugh B. 23 (18%) had HCV, 7 (5.5%) had HIV, alcohol intake was > 80 gr in 11 (9%), 12 (9%) had HBsAg and 33 (26%) had IgM anti-Hbc. All patients were either HDV-RNA serum positive or displayed HDV-Ag in the liver on immunofluorescence. All patients were under surveillance with clinical exams and abdominal ultrasound every 6 months. Results: During follow-up, HCC developed in 37 (29%), ascites in 25 (20%), jaundice in 19 (15%), variceal bleeding in 4 (3%) and encephalopathy in 1 (1%), corresponding to a mean yearly incidence of 3.2%, 2.1%, 1.6%, 0.3% and 0.1%, respectively. HCC was a single node in 19 (51%) with a mean diameter of 25mm. During follow-up, 14 (11%) patients progressed from Child-Pugh class A to B and 9 (7%) from Child B to C. 36 patients (28%) died, corresponding to a yearly mortality rate of 2.4%. Causes of death were liver failure in 22 (61%), HIV infection in 4 (11%), HCC in 2 (5%), variceal bleeding in 2 (5%), extrathoracic malignancies in 3 (8%), non liver related causes in 3 (8%). Conclusion:

Hepatitis Delta is a long-lasting compensated disease, whose major cause of death is liver decompensation.

INFLUENCE OF LIVER FIBROSIS ON HIGHLY ACTIVE ANTIRETROVIRAL THERAPY-ASSOCIATED EPATOTOXICITY IN HIV POSITIVE PATIENTS
Nicoletta Marino, Sergio Lo Caputo, Piera Pierotti, Claudio Blé, Francesco Mazzotta; Infectious Diseases, S.M.Annunziata Hospital, Firenze, Italy

Background -The effects of hepatic fibrosis on HAART-associated hepatotoxicity are not well understood due to the fact that it is hard to perform liver biopsy to all patients. Transient elastography is a non-invasive method for assessing liver fibrosis by measuring liver stiffness. The aim of this study was to evaluate the relationship between liver fibrosis and the rate of HAART-associated liver toxicity. Methods: Prospective cohort study of 353 consecutive HIV+ patients who underwent Liver Stiffness Measurement between January-December 2006. Liver fibrosis was staged using a scoring system of 0 (no fibrosis) to 4 (cirrhosis): < 7.1 KPa for F0/F1; 7.1 to 9.4 KPa for F2; 9.5 to 12.5 KPa for F3 and >12.5 KPa for F4. Hepatotoxicity was defined as an increase in AST/ALT levels over 5 times the upper limit of normal (ULN), or 5 fold increase if baseline levels were abnormal, with no other known precipitating cause and occurring in the last 3 years. The incidence of hepatotoxicity was compared with liver fibrosis stage and HAART duration plus HAART regimen. Backward stepwise logistic regression was employed for statistical analysis. Results: In the study population mean age was 44 yrs; 262/353 (74%) patients were male, 158/ 353 (45%) IDU, 191/353 (54%) HCV+, 22/353 (6,2)% HBV+ and 151/353 (42,8%) HIV + alone. 81/353 (22,9%) patients showed advanced liver fibrosis (>9,5 KPa). Significant hepatic fibrosis was strongly associated with HCV positivity (p <0.001) and significantly associated with AST level (p 0.010), IDV risk (p 0.23), GGT level (p 0.23). 7/353 (1,9%) patients with HIV+ alone and without risk factor for liver disease showed advanced liver fibrosis (all patients were MSM, with lower CD4 count [p ns], elevated ALT [p 0.01], without metabolic complications). There was no association between liver fibrosis and HAART regimen or cumulative period of ARV. Overall, there were 26 episodes (7,4%) of hepatotoxicity degree 3-4. All the events were asymptomatic, and no therapy was changed. There was no association between liver toxicity and age, sex, risk practice, CD4+ count, or HIV RNA level and a specific drug or regimen of HAART. A significant association was observed with liver fibrosis (p <0.041) and ALT level (p <0.001). Conclusions: In HIV infected patients, stage of liver fibrosis could be the most important factor for the risk of hepatotoxicity: patient with advanced liver fibrosis should be monitored more closely during HAART.

1472 FIBROSIS PROGRESSION RATE AND PORTAL PRESSURE IN RELATION TO CD4 CELL COUNT IN HIV-HCV COINFECTION

Thomas Reiberger¹, Wolfgang Sieghe1, Arnulf Fertlitsch1, Armin Rieger2, Brigitte Schmied3, Markus Peck-Radosavljevic1; ¹Department of Gastroenterology & Hepatology, Medizinische Universität & AKH Wien, Vienna, Austria; ²Department of Immunology & Dermatology, Medizinische Universität & AKH Wien, Vienna, Austria; ³Department of Pneumology, Otto-Wagner Hospital, Vienna, Austria

In the HAART era HCV-related liver disease is a leading cause of morbidity & mortality in HIV infection. Reasons for the higher HCV-RNA load and the more rapid fibrosis progression rate (FPR) in HIV-HCV-coinfected patients are not completely clear, so our aim was to identify risk factors for this accelerated course of liver disease. Methods: We analyzed data of 33 HIV-HCV-coinfected patients. All had liver biopsy, indirect measurement of portal pressure (hepatovenous pressure gradient=HVPG) and routine laboratory tests (including CD4 cell count, HIV & HCV viral load). IVD abuse was the main transmission route, so the estimated time of infection was recorded as the date of initial exposure (IVD injection). Results: Median age was 38 years, median BMI was 20.8 kg/m² and median CD4 count was 545/µL. HCV viral load was undetectable in 17 patients, 16 had a median HCV viral load of 3.98 log/mL. HCV-HIV patients had accelerated FPR (0.176 METAVIR fibrosis units/year [FU/y]), accelerated time to cirrhosis (TTC=25.7 years), high HCV viral loads (3.38x10⁶ IU/ml) and a mean HVPG at the upper limit of normal (5mmHg). In case of advanced immunodeficiency (previous CD4 cell nadir <200/µL) the FPR was even higher compared to patients with a CD4 cell nadir >200/µL (0.231 vs 0.140 FU/y). A highly significant indirect correlation between CD4 cell count and FPR (r=0.662; p<0.001; see figure) could be demonstrated. 19 patients received HAART, but HAART itself had no influence on FPR and HVPG. Conclusion: Progression of HCV disease is accelerated in HIV-HCV-coinfection, which is even more pronounced when CD4 cell count is low. A history of a CD4 cell nadir <200 µL is a risk factor for rapid development of cirrhosis. Thus, HCV treatment should be considered early in HIV-HCV-coinfection, when CD4 cell counts are high. Before initiation of HCV therapy, HAART can probably slow down liver disease progression by prevention of CD4 cell nadir values <200/µL.

1473 CLINICAL AND LABORATORY CHARACTERISTICS OF PREGNANT WOMEN CHRONICALLY INFECTED WITH HEPATITIS B VIRUS (HBV)

Kejia Wan¹, Thomas Miyoshi², Chia-hui Peng¹, Neetu K. Sadhi¹, Paige Baker¹, Sindy Yu¹, George Fryer², Henry Pollack¹; ¹Saul Krugman Division of Pediatric Infectious Diseases, NYU School of Medicine, New York, NY; ²NYU Center for Child Health Research, NYU School of Medicine, New York, NY

Most states in the U.S. mandate HBsAg testing of all pregnant women during prenatal care in order to prevent mother-infant transmission. The clinical and laboratory characteristics of hepatitis B virus (HBV) infection in these women are largely unknown. In this study, we reviewed the records of all HBV-infected women who received care in Prenatal Clinics at Bellevue Hospital and Gouverneur Healthcare Services in NYC between 2004 and 2006. Analysis was conducted retrospectively, through electronic medical record review of de-identified data, after IRB-approval. Out of 7354 pregnant women tested for HBV, 352 (4.8%) were HBsAg+. The median age of HBV-infected women was 27.1±5.3 years with a median age of 26.0 years. 82.1% were Asian/Pacific Islanders (APIs). 336 (95.5%) was tested for ALT, 318 (90.3%) for HBeAg, and 187 (53.1%) for HBV DNA. Women with elevated ALT were more likely to be tested for viral load than those with normal ALT (87.5% vs. 53.4%, p<0.01) as were women who were HBeAg+ compared to those who were HBeAg- (65.3% vs. 47.4%, p<0.01). 39.0% (124/318, 95% CI: 33.7, 44.4) of the women were HBeAg+, and 4.8% (16/336, 95% CI: 2.8, 7.4) had elevated ALT (>2 x ULN). ALT levels ranged from 5 to 207, with a mean of 27 IU/mL. The median viral load was 1.0 X 10⁴ copies / ml and mean viral load 1.8 X 10⁸ copies / ml. The median viral load was 1.0 X 10⁴ copies / ml and mean viral load 1.8 X 10⁸ copies / ml. HBeAg was detected in 37.9% (124/318, 95% CI: 33.7, 44.4) of the women who had a viral load measurement. 29 (35.8%, 95% CI: 26.0, 46.5) had a viral load > 5.5 X10⁸ copies/ml and at least 11 (13.6%) had a viral load > 10⁹ copies/ml. In conclusion, among HBsAg+ pregnant women in this study, 80% had active infection, almost 50% were at risk of significant future complications of chronic HBV infection, and as many as 13% may have had viral loads >10⁹ copies/ml, associated with a higher risk of neonatal HBV prophylaxis failure. This analysis should be valuable for estimating the burden of HBV-related disease and projecting the cost of care among pregnant women with chronic HBV infection. Recommendations for the evaluation and care of women identified by prenatal HBV screening would be of great value for this vulnerable population as the diagnosis of hepatitis B during pregnancy is an opportune time to provide proper evaluation of risk for future HBV-related complications and the need for HBV-specific treatment.

1474 BARRIERS TO VIRAL HEPATITIS TREATMENT FOR AT-RISK GROUPS: IMPACTS OF POLICIES AND PROCESSES

Amy B. Jessop¹, Monika Burke²; ¹HepTREC, Ardmore, PA; ²Gastroenterology Section, Temple University, Philadelphia, PA

Background: Hepatitis B and C viruses infect an estimated 4.5 million Americans. We know that much morbidity and mortality can be prevented through awareness, preventive behaviors, and treatment. Unfortunately, population groups most impacted
by hepatitis C (racial and ethnic minorities, people with drug, alcohol, and incarceration histories) are typically least able to negotiate the policy and healthcare systems in order to receive optimum care. This project examined barriers to hepatitis C prevention, diagnosis, and especially treatment for at-risk population groups in the Philadelphia, PA region. Methods: Methods of data collection included key informant interviews, extensive literature review, and focus group and individual interviews. Target groups included current or former substance users, currently or formerly incarcerated individuals, MSM, HIV infected adults, and African American, Hispanic, and Asian men and women ages 18-40. Analysis was iterative and inductive. We generated general themes or categories of barriers, identified consensus in the three sources, examined the context of the barriers for our target populations, and identified potential means to overcome barriers. Results: Three barrier categories were identified: Structural Barriers, Social/Community Barriers, and Individual Barriers. Barriers from one category frequently overlapped, exacerbated or created barriers within other categories. We present actions or changes that could be implemented within medical communities, government agencies, insurance providers, and community agencies to remove or alleviate barriers to hepatitis care. Conclusions: Most barriers can be addressed through policy and procedure changes. Others can be addressed through carefully designed awareness and education programs for medical providers, social service agency personnel, hepatitis patients and the general public.

1475 ANTI-HBV THERAPY CAN REDUCE HEPATITIS DELTA REPlication IN HIV-coinfected Patients
Julie Sheldon2, Carlos Toro2, Belen Ramos2, Pilar Rios2, Jose Martinez-Alarcon2, Miriam Romero1, Javier Garcia-Samaniego1, Vicente Soriano2; 1Hepatology Unit CIBEREHD, Carlos III Hospital, Madrid, Spain; 2Infectious Diseases, Hospital Carlos III, Madrid, Spain

Background: HDV has a unique replication process using the host cellular polymerase. For this reason together with its high pathogenic potential, chronic hepatitis Delta (CHD) is very challenging. No specific inhibitor of HDV has so far been developed, and treatment is currently limited to intensive interferon-based therapy. However, the role of potent nucleos(t)ide analogues against chronic HDV infection has not been well examined. Methods: A longitudinal study was carried out in all HIV-positive patients with CHD whom attended our hospital. Serum HBV DNA for each patient was longitudinally determined using Cobas HBV Taqman PCR (Roche, LDL 12 IU/ml), and serum HDV RNA was quantified using an in-house real time PCR assay (LLD, 100 cop/ml) at yearly intervals. Treatment regimens, plasma HIV and when pertinent HCV RNA, CD4 counts, ALT/AST levels and liver fibrosis measured by FibroScan® were also assessed. All statistical analyses were made using SPSS v12. Results: A total of 18 HIV-positive patients with CHD were identified, the majority male (83%). Median age was 33 years and baseline ALT, HIV RNA, HBV DNA, and CD4 were 98 IU/ml, 1.69 log10 copies/ml, 1.19 log10 IU/ml, and 344 cells/ml, respectively. Median follow-up was 6 years. All had detectable serum HDV RNA before receiving any anti-HBV treatment (median: 6.5 log10 cop/ml). A statistical significant correlation between HBV and HDV viral load was found (r=0.259; p=0.005). Anti-HBV drugs used were lamivudine (n=17), tenofovir (n=11) and/or emtricitabine (n=5). Overall, 11 patients showed good response to anti-HBV therapy achieving undetectable HBV DNA for a minimum of 2 years. Moreover, all of them showed a statistically significant decrease in plasma HDV RNA (mean: 1.44 log10 cop/ml, p=0.038) and ALT levels (mean: 45 IU/ml, p=0.022). In fact, 3 of these patients (1 received lamivudine and 2 lamivudine + tenofovir) achieved undetectable HDV RNA (<100 cop/ml) after a mean of 5.6 years of HBV antiviral therapy. Conclusion: Patients undergoing successful anti-HBV therapy with potent nucleoside analogs seem to have an indirect benefit for suppressing HDV replication, albeit not very efficient. Hypothetically, a significant and sustained reduction in serum HDV RNA may only be seen when a reduction in HBV cccDNA or HBsAg is achieved, which may require long periods of successful anti-HBV therapy. To our knowledge, this is the first clear evidence of benefit of potent anti-HBV nucleos(t)ide analogue therapy in CHD.

1476 ACUTE HEPATITIS E: RESULTS OF A FRENCH SURVEY
Christophe Renou1, Xavier Moreau2, Jean-François Cadranel3, Elisabeth Nicand4, Thierry Morin5, Yves Botreau6, Marc Bourniére2, François Combet2, Yves Imbert2, Frédéric Heluaert10, Dominique Louvel1, Valérie Oulès4, Alexandre Païenti12, Jean-Louis Payen13, Eric Poncin14, Hervé Rifflet15, Isabelle Rosa19, Valérie Rossi17, Nicole Pavio18, 1CH d’Hyères, Hyères, France; 2Polyclinique Malartic, Ollioules, France; 3CH de Creil, Creil, France; 4Val de Grâce, Paris, France; 5CH de Tarbes, Tarbes, France; 6CH de Cahors, Cahors, France; 7Hôpital Saint-Joseph, Marseille, France; 8CH de Privas, Privas, France; 9CH d’Agen, Agen, France; 10CH de la Région d’Annecy, Annecy, France; 11CH de Cayenne, Cayenne, France; 12CH de Pau, Pau, France; 13CH de Montauban, Montauban, France; 14CH de Dax, Dax, France; 15CH d’Ajaccio, Ajaccio, France; 16CH de Créteil, Créteil, France; 17CH du Haut Anjou, Chateau-Gontier, France; 18Ecole Nationale Vétérinaire d’Alfort, Maisons-Alfort, France

The incidence of sporadic hepatitis E has been increasing in France, as in other industrialized countries, during the last few years. Several studies have suggested the autochthonous nature of many recent cases of acute hepatitis E, although the source of contamination and the transmission pathways involved have not yet been determined. The aim of this French survey was 1) to draw up an overall picture of recent hepatitis E cases at the participating hospitals since January 2004, 2) to determine whether or not the majority of these cases of hepatitis E are autochthonous and to describe their characteristics, 3) to attempt to determine the sources of contamination possibly responsible for autochthonous cases of hepatitis E. The response rate to an e-mail sent in October 2006 to all French General Hospitals was 34% (65/190). Fourteen of the 65 hospitals contacted reported a total number of 33 cases (10, 8, 3, 2, 1 cases in 1, 1, 1, 1, 10 hospitals, respectively). A North-South (5 cases/27 cases) and a West-East (11 cases/21 cases) gradient were found to exist (plus 1 case in French Guiana). However, the former gradient resulted from a small-scale outbreak in a single department in the South of France (18 cases occurred in the department of the Var). The number of cases increased during the 3 years of retrospective recruitment (3 cases in 2004, 10 cases in 2005, 20 cases in 2006). The presence of HEV was diagnosed by elimination, in addition to elevated ALT levels above 300 IU/ml associated with a strong
reactivity for HEV-specific antibodies with or without detectable HEV-RNA (in the serum and/or stools). Mean age of the 33 patients (23 men and 10 women) was 53±15 years. The first clinical symptom was jaundice (19 cases), either alone or associated with fever, flu-like symptoms and vomiting. The diagnosis was based on the serological results in 29 cases, and on both serological and virological tests in the other four cases. Thirty-one patients had no history of travel outside Europe or any contacts or relationships with persons who had been in an endemic country 3 months before the first symptoms occurred, whereas two patients had travelled to Algeria and Pakistan during this period. Among the group of 31 patients who had not been out of Europe, the most relevant and frequent risk factors were direct or indirect consumption of water from a personal well or a nearby river (13 cases) and eating sea-food (7 cases). This survey confirms the recent increase in the incidence of autochthonous acute hepatitis E in France, for which the consumption of contaminated food or water might be mainly responsible.

1477
HEPATITIS D (HDV) AND B (HBV) VIRUSES GENOTYPES IN CHRONIC LIVER DISEASE PATIENTS FROM EASTERN AMAZON BASIN

Michele S. Gomes-Gouveia1, Manoel P. Soares2, Isabel M. Mello3, Elizabete F. Brito4, Lizamar P. Miora5, Gilberta Bensabath6, Heloisa M. Nunes6, Flair J. Carrilho7, Joao R. Pinho1; 1Departamento de Gastroenterologia, Faculdade de Medicina / Instituto de Medicina Tropical do UFP, Sao Paulo, Brazil; 2Seção de Hepatologia, Instituto Evandro Chagas, Belem, Brazil; 3Laboratório de Imunologia Viral, Instituto Butantan, Sao Paulo, Brazil; 4Programa de Hepatopatias Crônicas, Fundação Santa Casa de Misericórdia do Pará, Belem, Brazil

HDV is a defective hepatotropic virus which infectivity is dependent on HBV. HDV super or co infection is a major health risk in chronic or acute HBV infected patients due to the increased risk of fulminant hepatitis or progression to severe chronic liver disease. In some regions of South America, such as Western Amazon Basin, HDV infection have been associated with hepatitis outbreaks of particularly high morbidity and mortality. HDV is classified in 7 major clades (HDV1 to HDV7) with strong phylogenetic support. The aim of this study was to characterize HBV and HDV genotypes harbored by chronic carriers from the Eastern Amazon Basin. We studied 17 samples from HBV and HDV chronic patients from the Eastern Amazon basin, Brazil, admitted to a large public hospital (Santa Casa de Misericórdia) at Belém, Pará, Brazil, between 1994 and 2002. HDVRNA and HBVDNA were detected by polymerase chain reaction (PCR). For HDV, the partial delta antigen genomic region (403 nucleotide fragment) and for HBV, a 416 nucleotide fragment covering a conserved region of the surface antigen coding gene, were amplified. Both strands of the second PCR products were submitted to cycle sequencing with the ABI Prism BigDye terminator cycle sequencing ready reaction Kit (Applied Biosystems, Foster City, CA, USA). A multiple sequence alignment of the analyzed regions and the related sequences in the GenBank/EMBL database was performed with ClustalX. The substitution model was selected with modeltest 3.06. Maximum-likelihood phylogenetic analyses were performed with PAUP*4.0b10. Robustness of the phylogenetic groups was evaluated using 1000 bootstrap replicates. In this study, we have identified this HDV3 in all cases. Conversely to previous studies from other regions of the Amazon, in the present study, HBV genotype A (subtype adw2) was found co-infecting patients harboring HDV3. The finding of the co-infection HDV3/HBV-A suggest that there is not an specific interaction between HBV and HDV genotypes, but that this co-infection merely reflects the most frequent genotypes found in a particular area. The analysys of the carboxy-terminal region of LHDag, which is related to the interactions to the HBsAg and essential to their binding, showed some diversity between the different isolates from Eastern Amazon. This region was highly conserved among previous South American isolates. These studies have analyzed a limited number of samples what may explain the smaller diversity but we cannot rule out the that HDV3 circulating in Eastern Amazon shows a higher degree of variability than in other regions. 1478
EXPRESSION OF TOLL-LIKE RECEPTOR 3 ON DENDRITIC CELLS IN CHRONIC HEPATITIS B VIRUS INFECTION

Baoyan An, Qing Xie, Hui Wang, Nina Jia, Honglian Gui, Xiaiqiu Zhou, Qing Guo, Hong Yu; Department of Infectious Diseases, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China

Background and aims: An inadequate immune response of host is thought to play a critical role in chronic hepatitis B virus infection (HBV). Dendritic cells (DCs) are professional antigen presenting cells that are pivotal in immune response. Toll-like receptors (TLRs) function as PRRs principally sense conserved molecule motif. TLR3 recognize dsRNA induce type I interferon. This study is to elucidate the roles of TLR3 on DCs in HBV infection. Methods: Monocytes were isolated from fresh peripheral blood of 22 healthy volunteers (HV) and 28 chronically HBV-infected patients (CH). DCs were induced and proliferated in the culture medium with recombinant human granulocyte-macrophage-colony-stimulating factor (rHGM-CSF) and human interleukin-4 (rhIL-4). The expressions of TLR3, HLA-DR, CD86, and CD1a on DCs were quantified by Flow Cytometry. We stimulated DCs with polyC: and examined TLR3, HLA-DR, CD86, and CD1a expression at 0 hours, 24 hours and 48 hours by Flow Cytometry. Results: TLR3 expression on DCs before and 12h, 24h, 48h after poly-inosinic acid-cytidylic acid (polyC) stimulation are 69%, 75%, 78%, 85% respectively in CH groups, whereas 70%, 67%, 86%, 68% in HV groups. The expressions of TLR3 up regulate significantly (P<0.01) at 24h and recover at 48h after stimulation with poly C in HV groups, whereas, there are no significant increases at 24h but obvious increases were observed at 48h in CH groups. The rate of CD86 expression is 63%, 76%, 91%, 88% in CH groups, and 50%, 81%, 93%, 94% in HV groups at various time points after Polyc stimulation. There was a marked increase of the expression level of CD86 in HV groups (P<0.01). In contrast, only slight increase was found in CH groups (31% vs 13%). The differences (P<0.01) between the groups were maintained at 24h and 48h. No significant differences were detected in HLA-DR and CD1a between two groups. Conclusions: The increase of expression level of TLR3 is slower and delayed in CH groups. A marked increase of the expression level of CD86 is observed in HV groups, whereas, only slight increase was seen in CH
groups. Our results suggest that abnormal expression of TLR3 and CD86 may lead to persistent infection of HBV.

1479 PRIMARY CARE PROVIDER ADHERENCE TO HCV TESTING RECOMMENDATIONS
Maricruz Velez1, David N. Assis2, Marta Alvarez-Posadilla3, Steven K. Herrine1, Simona Rossi1, Victor J. Navarro1; 1Division of Gastroenterology & Hepatology, Thomas Jefferson University, Philadelphia, PA; 2Department of Medicine, Thomas Jefferson University, Philadelphia, PA; 3Sección de Aparato Digestivo, Hospital de León, Leon, Spain

Background: Published guidelines regarding HCV testing practices are infrequently followed (Trooskin, 2007). Therefore, the aim of this study was to survey primary care provider adherence to testing recommendations and to identify provider and practice characteristics associated with lack of adherence. Methods: A survey was mailed to 2,365 primary care providers in the Philadelphia area. Analyses investigated the association between provider and practice characteristics with responses to 16 clinical scenarios reflecting HCV testing guidelines. A score from 0-16 was generated for each respondent, with 0 indicating all incorrect responses and 16 indicating all correct responses. Analyses were carried out in SAS 9.1. Results: A total of 1,219 surveys were returned (58% response); 1,205 surveys were included in the analysis. The mean age of respondents was 50 years, 73% were male and 83% self-identified as non-Hispanic white. Fifty-one percent were internists; 17% were assistants; 67% were in private practice, 59% were in a suburban area. The mean adherence score was 9.6. Most providers (74%) reported that they would test patients based on race alone (African American or Hispanic). Most HIV-infected patients will receive anti-HBV as part of ART and were thus considered baseline. ANOVA was used to compare continuous variables across the three groups and chi-squared for dichotomous variables. Results: ESLD and cirrhosis was seen more frequently in those with HIV/HCV/HBV compared to those with HIV/HCV or HIV/HBV (p=0.02 and 0.03, respectively). Log HCV load was similar in those with HIV/HCV (5.08) vs. triple (5.37). Log HBV DNA was lower in those with triple (2.58) compared to those with HIV/HBV (7.25), p=<0.001, however many samples in the triple group were obtained while patients were on ART, often using nucleosides with anti-HBV activity. Baseline samples [HIV/HBV (n=55); HIV/HCV (n=12); triple (n=13)] were examined and showed no difference in HCV viral load between HIV/HCV and triple infection, but log HBV viral load was slightly lower in those with triple infection compared to those with HIV/HBV (5.06 vs. 7.25, p=0.07). A history of alcohol abuse was more frequent in those with HCV/HCV compared to those with HIV/HBV (p=0.06 and 0.03, respectively). Conclusions: HIV-infected patients with both HBV and HCV are more likely to progress to ESLD compared to those with HIV/HBV or HIV/HCV. Cirrhosis is also more likely to be seen in this population. Most HIV-infected patients will receive anti-HBV as part of ART. Triply infected patients should be considered additionally for HCV treatment, given the propensity for disease progression. 1480 LIVER DISEASE PROGRESSION AMONG HIV-INFECTED PATIENTS WITH VIRAL HEPATITIS
Emmanuel Seremba, Reeti K. Joshi, Nahid Attar, William M. Lee, Mamta K. Jain; Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX

Background: Co-infection with viral hepatitis B (HBV), C (HCV) or both is common in HIV-infected patients due to shared routes of transmission. Little is known about the risk of liver disease progression among those coinfected with HIV/HCV, HIV/HBV or triply infected with HIV/HBV/HCV. Methods: Medical records of 151 HIV-infected patients including 67 HIV/HBV, 43 HIV/HCV, and 41 triply infected patients were reviewed for demographics, CD4 cell count, HIV viral load, liver function tests, hepatitis B, C, and hepatitis delta (HDV) serologies, and radiologic images. Charts were reviewed in 124 for evidence of progression to end stage liver disease (ESLD) and alcohol consumption. HBV DNA was quantified using VERSANT® HBV 3.0 (bDNA) and HCV RNA with VERSANT® HCV RNA 3.0 (Siemens Diagnostics, Tarrytown NY) from stored sera. Eighty samples were obtained prior to start on antiretroviral therapy (ART) and were thus considered baseline. ANOVA was used to compare continuous variables across the three groups and chi-squared for dichotomous variables. Results: ESLD and cirrhosis was seen more frequently in those with HIV/HCV/HBV compared to those with HIV/HCV or HIV/HBV (p=0.02 and 0.03, respectively). Log HCV load was similar in those with HIV/HCV (5.08) vs. triple (5.37). Log HBV DNA was lower in those with triple (2.58) compared to those with HIV/HBV (7.25), p=<0.001, however many samples in the triple group were obtained while patients were on ART, often using nucleosides with anti-HBV activity. Baseline samples [HIV/HBV (n=55); HIV/HCV (n=12); triple (n=13)] were examined and showed no difference in HCV viral load between HIV/HCV and triple infection, but log HBV viral load was slightly lower in those with triple infection compared to those with HIV/HBV (5.06 vs. 7.25, p=0.07). A history of alcohol abuse was more frequent in those with HIV/HCV compared to those with HIV/HBV (p=0.06). Conclusions: HIV-infected patients with both HBV and HCV are more likely to progress to ESLD compared to those with HIV/HBV or HIV/HCV. Cirrhosis is also more likely to be seen in this population. 1481 DIAGNOSTIC ACCURACY OF BLOOD TESTS OF LIVER FIBROSIS IN CHRONIC HEPATITIS B: COMPARISON WITH HEPATITIS C
Vincent Leray, Nathalie Sturm, Marie-Noelle Hilleret, Renversez Patrick, Candice Trocmé, Faure Patrice, Jean-Pierre Zarski; CHU de Grenoble, Grenoble, France

Several blood tests are currently used for the non-invasive evaluation of liver fibrosis. They have been mainly described and validated in chronic hepatitis C (CHC). Their diagnostic accuracy is however poorly documented in patients with chronic hepatitis B (CHB). The aim of this study was to describe the diagnostic performance of a panel of blood tests of fibrosis in CHB compared to CHC. Methods: 510 patients seen in our center for a pre-therapeutic liver biopsy between 2000 and
2007 were recruited. They included 255 CHC patients and 255 CHB (monoinfected) patients, matched on the stage of fibrosis. Blood tests (Fibrotest, Hepascore, Fibrometer and MP3) were assessed on frozen serums collected the day of the biopsy. Histological lesions were staged according to the METAVIR system. Perisinusoidal fibrosis was noted. Areas of fibrosis were quantified by morphometry in 100 patients (20 per stage of fibrosis). Results: CHC were significantly older (47 vs 40 years, p<0.01), had lower ALT levels (73 vs 93 UI/ml, p<0.005) and higher GGT levels (91 vs 53 UI/ml, p<0.01) than CHB patients. Other characteristics including alcohol consumption, Metavir activity and biopsy length (median 23 mm) were similar. Fibrosis stages were distributed as follow : F0 n=72, F1 n=192, F2 n=132, F3 n=54, F4 n=56. Diagnostic accuracies of blood tests for significant fibrosis (F0F1 vs F2F3F4) were compared between CHC and CHB and were as follow (AUROCs) : Fibrometer : 0.81 vs 0.82, Fibrotest : 0.81 vs 0.78, MP3 : 0.80 vs 0.76 Hepascore : 0.79 vs 0.77. For the diagnosis of extensive fibrosis the best result was observed for Fibrometer (0.89 vs 0.89). Test performance profiles were also evaluated. The rate of misclassification was significantly higher in CHB compared to CHC in patients with early stages of fibrosis (F0F1F2) (41% vs 30%, p<0.01 for Fibrotest). This was especially true for discriminating F1 vs F2. Morphometric analysis showed a significant correlation between area and stage of fibrosis (r=0.82, p<0.001), with the notable exception of F1 vs F2 (4.1 vs 4.0%, NS). Comparisons between CHC and CHB for F0, F1 and F2 stages showed greater areas of fibrosis in CHC (on average 2-fold, p<0.001), that was explained in part by more pronounced perisinusoidal fibrosis in CHC. No difference was observed between CHC and CHB for F3F4 stages.

Conclusion: Our results show that in CHB blood tests of fibrosis have good global diagnostic accuracies especially for the diagnosis of extensive fibrosis. However, test performance profiles are altered in early stages of fibrosis (F0F1F2), a result explained by a different distribution of liver fibrosis in CHB compared to CHC.

Disclosures: The following people have nothing to disclose: Vincent Leroy, Nathalie Sturm, Marie-Noelle Hilleret, Renversez Patrick, Candice Trocmé, Faure Patrice, Jean-Pierre Zarski
